**Impact of two ECAL options
Invisible higgs decay**

July, 22, 2014
T. Ogawa

Upper Limit of BR(H→invisible)

1. $\sqrt{s}=250\text{GeV}$ (250fb^{-1}).

Si: $\epsilon_{\text{sig}}=70.46[\%]$, $N_{\text{sig}}=448$

→ $\sigma = 2.54[\text{fb}]$

BR(H→invisible) < 1.20% @95% C.L.

Sc: $\epsilon_{\text{sig}}=71.03[\%]$, $N_{\text{sig}}=503$

→ $\sigma = 2.83[\text{fb}]$

BR(H→invisible) < 1.33% @95% C.L.

→ The degradation of sensitivity is 11%

2. $\sqrt{s}=350\text{GeV}$ (350fb^{-1}).

Si: $\epsilon_{\text{sig}}=53.20[\%]$, $N_{\text{sig}}=622$

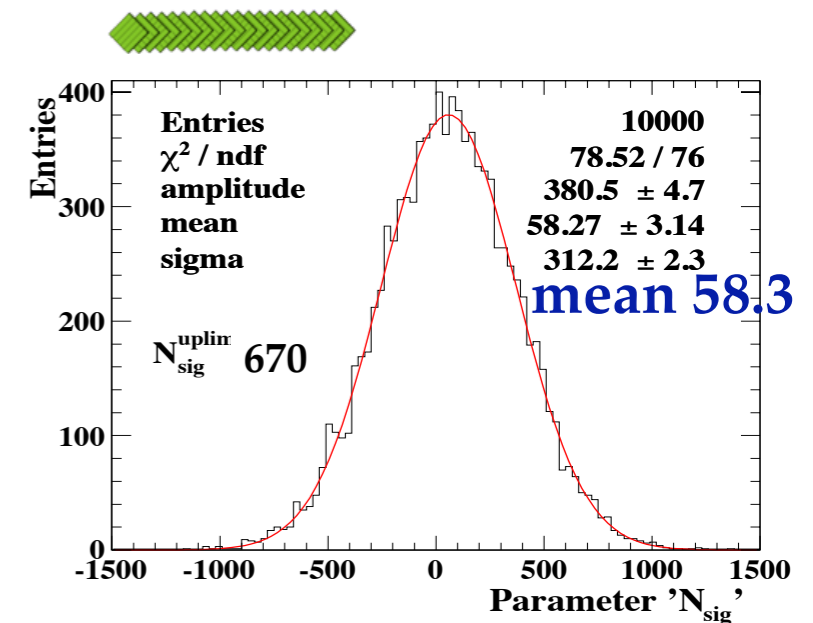

→ $\sigma = 3.35[\text{fb}]$

BR(H→invisible) < 2.43% @95% C.L.

Sc: $\epsilon_{\text{sig}}=53.82[\%]$, $N_{\text{sig}}=670$

→ $\sigma = 3.56[\text{fb}]$

BR(H→invisible) < 2.58% @95% C.L.

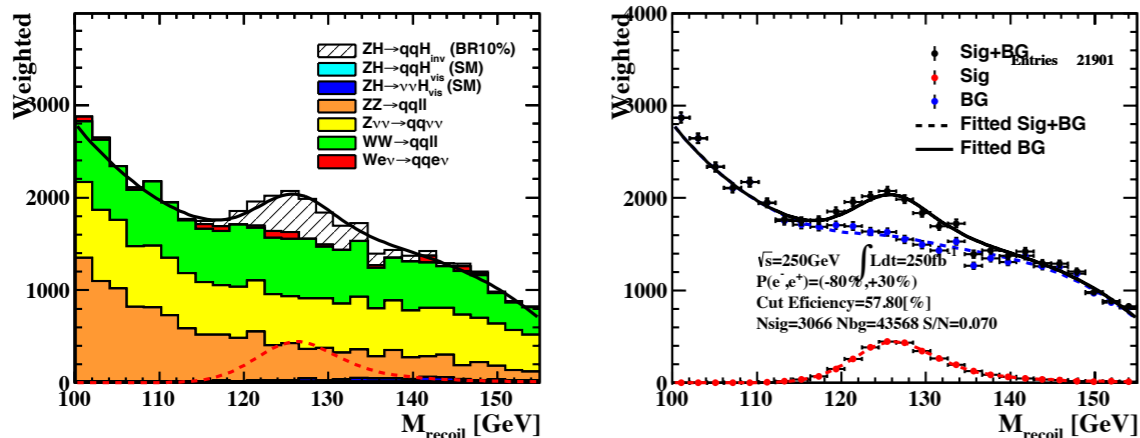

→ The degradation of sensitivity is 6.3%

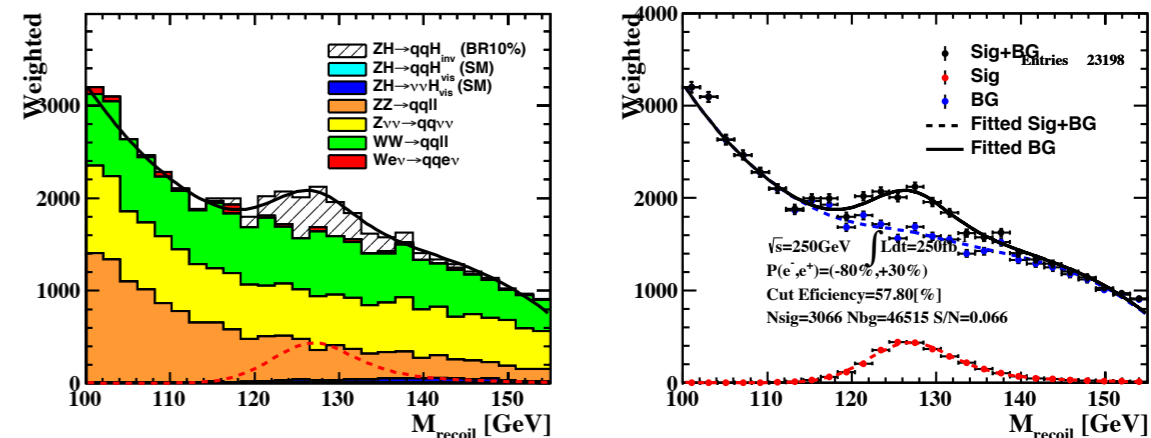

$\sqrt{s}=250\text{GeV}$ (250fb⁻¹).

- 1. Applied more tight M_z cut.
- 2. GPET + 3rd Pol

Si ECAL

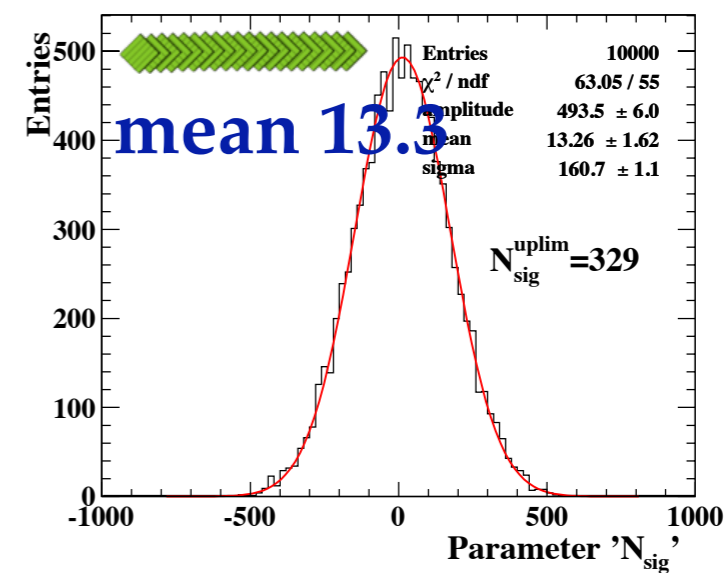

Sc ECAL

ToyMC

$\epsilon_{\text{sig}} = 57.80\%$, $N_{\text{sig}} = 315 \Rightarrow \sigma = 2.18[\text{fb}]$
 $\text{BR}(H \rightarrow \text{invisible}) < 1.03\% @95\% \text{C.L.}$

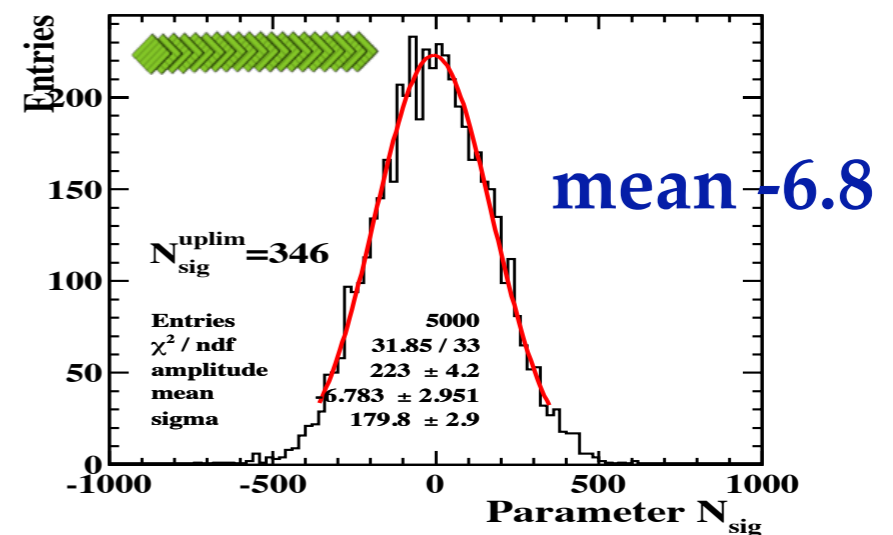

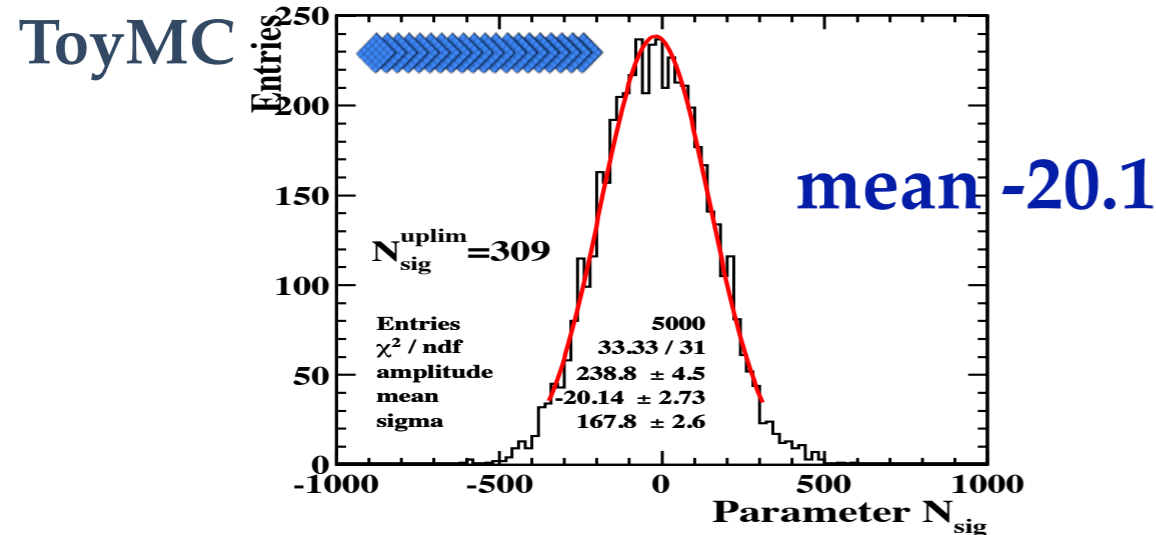

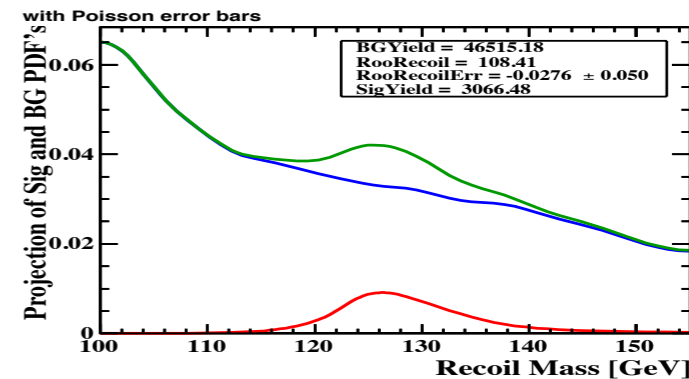

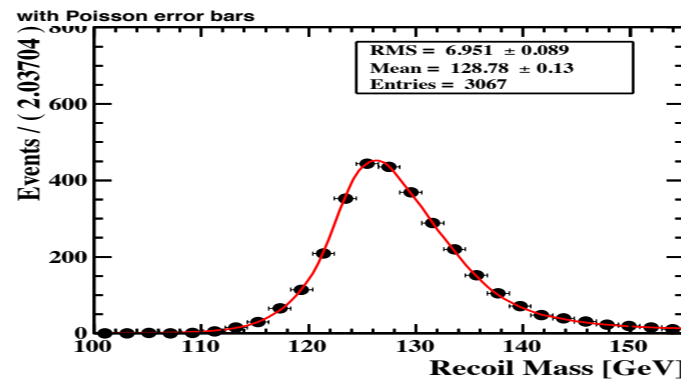

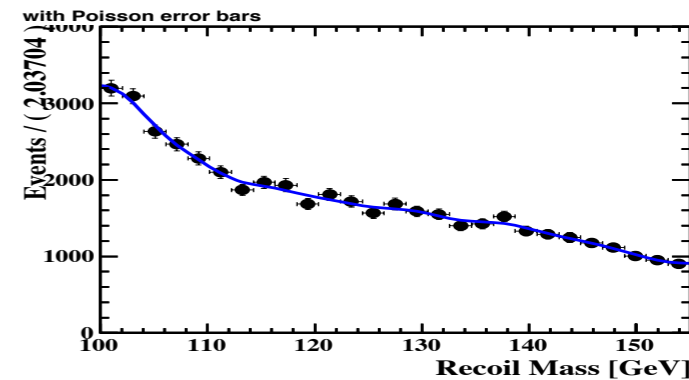

$\epsilon_{\text{sig}} = 57.80\%$, $N_{\text{sig}} = 329 \Rightarrow \sigma = 2.28[\text{fb}]$
 $\text{BR}(H \rightarrow \text{invisible}) < 1.07\% @95\% \text{C.L.}$

For now the difference is only 0.05%
 \Rightarrow The degradation of sensitivity is 3.8%

still biased

$\sqrt{s}=250\text{GeV}$ (250fb⁻¹).

- 1. Kernel (sig) + Kernel (bg)

$\epsilon_{\text{sig}} = 57.80\%$, $N_{\text{sig}} = 309 \Rightarrow \sigma = 2.14[\text{fb}]$
 $\text{BR}(H \rightarrow \text{invisible}) < 1.01\% @95\% \text{C.L.}$

$\epsilon_{\text{sig}} = 57.80\%$, $N_{\text{sig}} = 346 \Rightarrow \sigma = 2.40[\text{fb}]$
 $\text{BR}(H \rightarrow \text{invisible}) < 1.13\% @95\% \text{C.L.}$

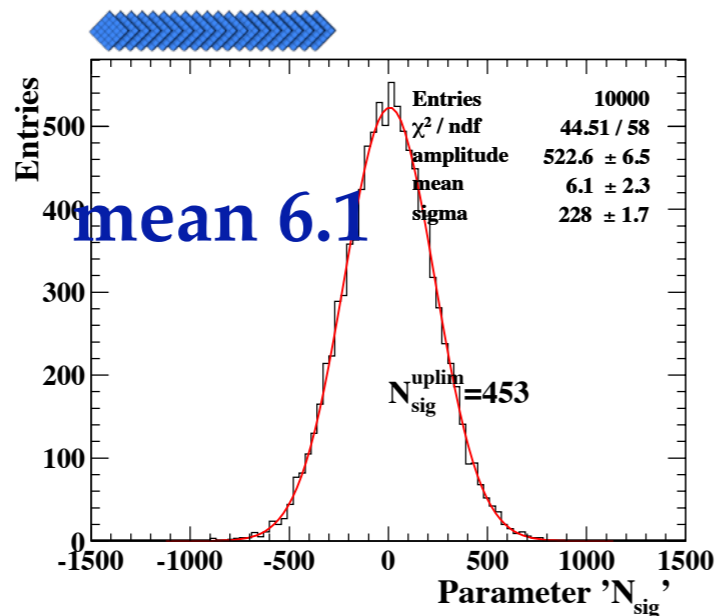

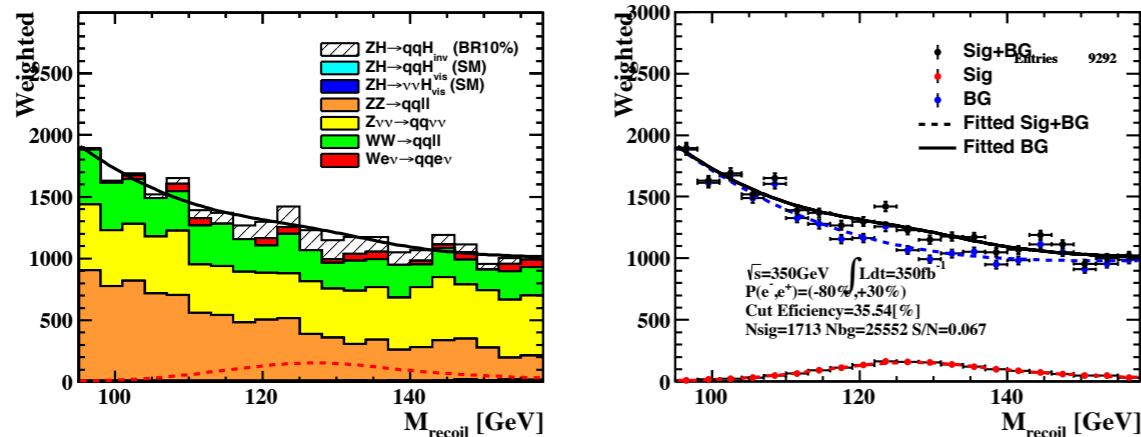

For now the difference is only 0.12%
 \Rightarrow The degradation of sensitivity is 12%

not good

$\sqrt{s}=350\text{GeV}$ (350fb⁻¹).

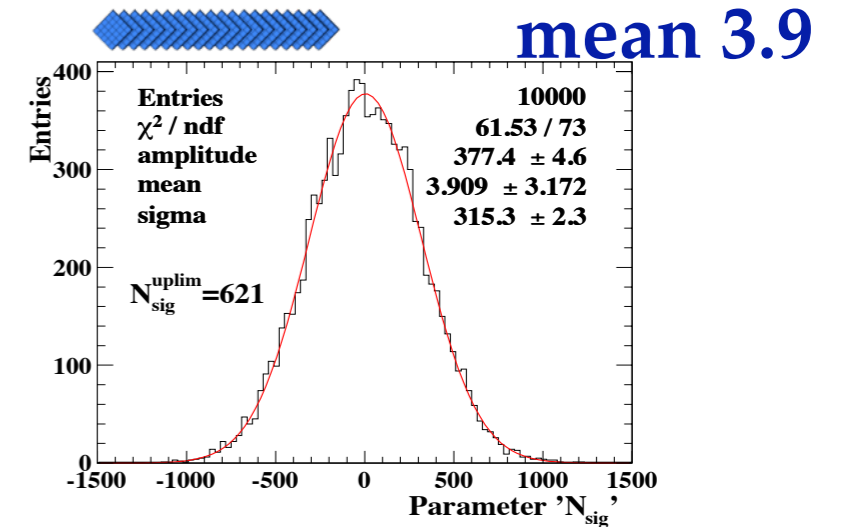

- Applied more tight M_z cut.
- GPET + 3rd Pol

Si ECAL

$\epsilon_{\text{sig}}=35.54\%$, $N_{\text{sig}}=453 \Rightarrow \sigma = 3.62[\text{fb}]$
 $\text{BR}(H \rightarrow \text{invisible}) < 2.64\% \text{ @}95\% \text{ C.L.}$

Previous result

Si: $\epsilon_{\text{sig}}=53.20\%$, $N_{\text{sig}}=622 \Rightarrow \sigma = 3.35[\text{fb}]$
 $\text{BR}(H \rightarrow \text{invisible}) < 2.43\% \text{ @}95\% \text{ C.L.}$

need to optimize cut parameter

Next step

- Need to modify seed sample.

- To reject bias of fitting function.

- Need to consider two BG processes like signal process.

$$ZH \rightarrow q\bar{q}ZZ^* \rightarrow q\bar{q}vvvv$$

Z

$$ZH \rightarrow \nu\nu ZZ^* \rightarrow \nu\nu q\bar{q}\nu\nu$$

Z

- Concerning fitting function itself.

- Search good result while changing cut parameter.
