## Probing CPV mixing in the Higgs sector in VBF at 1 TeV ILC

N. Vukasinovic, I. Bozovic Jelisavcic, G. Kacarevic

*on behalf of the ILD Detector Concept Group*

VINCA Institute of Nuclear Sciences,  
Belgrade, Serbia

## OPENING QUESTIONS/OUTLINE

1. Could 125 GeV Higgs mass eigenstate be a CPV mixture of CP-odd and CP-even states via mixing angle  $\Psi_{\text{CP}}$ ?
2. If so, with what precision  $\Psi_{\text{CP}}$  can be measured at 1 TeV ILC ?
3. What is the interpretation of measurement sensitivity (in the context of Snowmass CPV White paper [[arXiv:2205.07715v3](https://arxiv.org/abs/2205.07715v3)])?

# SENSITIVE OBSERVABLE

- Generic model of CPV mixing:  $h_{125} = H \cdot \cos \Psi_{CP} + A \cdot \sin \Psi_{CP}$
- CP-sensitive observable: angle between production planes  $\Delta\phi$
- As shown in [\[arXiv:2203.11707v2\]](https://arxiv.org/abs/2203.11707v2)  $\Delta\Phi$  carries the most information on Higgs CP state

$$\Delta\Phi = \begin{cases} \arccos(\cos \Delta\Phi), & \text{sgn}(\sin \Phi) \geq 0 \\ 2\pi - \arccos(\cos \Delta\Phi), & \text{sgn}(\sin \Phi) < 0 \end{cases}$$

$$\cos \Phi = (-\hat{n}_1 \cdot \hat{n}_2)$$

$$\text{sgn}(\sin \Phi) = \frac{\mathbf{q}_1 \cdot (\hat{n}_1 \times \hat{n}_2)}{|\mathbf{q}_1 \cdot (\hat{n}_1 \times \hat{n}_2)|} \quad \hat{n}_1 = \frac{q_{e_i^-} \times q_{e_f^-}}{|q_{e_i^-} \times q_{e_f^-}|} \quad \hat{n}_2 = \frac{q_{e_i^+} \times q_{e_f^+}}{|q_{e_i^+} \times q_{e_f^+}|}$$

# SIGNAL AND BACKGROUND

~ 1 TeV energies are optimal due to interplay of x-section and centrality

1 TeV	$\sigma$ (fb)	Expected in 8 ab <sup>-1</sup>	Reconstructed with ILD
SIGNAL: $e^+e^- \rightarrow H\bar{e}e, H \rightarrow b\bar{b}$	13	104000	200000 DELPHES 3495 full sim.
$e^+e^- \rightarrow q\bar{q}l^+l^-$	255	2·10 <sup>6</sup>	5886
$e^+e^- \rightarrow q\bar{q}$	9375	75·10 <sup>6</sup>	120343
$e^+e^- \rightarrow q\bar{q}lv$	4116	32.9·10 <sup>6</sup>	955058

	$\sqrt{s}$	beam polarisation	$\int L dt$ (baseline)
<b>ILC</b>	0.1 - 1 TeV	e <sup>-</sup> : 80% e <sup>+</sup> : 30% (20%)	2 ab <sup>-1</sup> @ 250 GeV 0.2 ab <sup>-1</sup> @ 350 GeV 4 ab <sup>-1</sup> @ 500 GeV 8 ab <sup>-1</sup> @ 1 TeV

- Generator level WHIZARD V2.8.3/UFO/Higgs characterization model signal and WHIZARD 1.95/SM background
- Unpolarized beams

# GENERATED AND RECONSTRUCTED SIGNAL

**Corrected** reconstructed signal for pure scalar  $\Psi_{CP}=0$ , **generated** information (WHIZARD) and **uncorrected** reconstructed signal

- Acceptance correction needed to retrieve full physical information
- Generated information is reasonably well reproduced with corrected reconstructed data

# EVENT SELECTION

## ○ Preselection – electron isolation:

- $m_{e^+e^-} > 200 \text{ GeV}$  (veto HZ)
- DELPHES electron isolation
  - $\Delta R_{\text{max}} = 0.5$
  - $p_{T\text{min}} = 0.5 \text{ GeV}$
  - $I = \frac{\sum_{i \neq P}^{p_T(i) > p_T^{\text{min}}} p_T(i)}{p_T(P)} < 0.12$
- Signal preselection efficiency: **~71%**

## ○ Selection cuts:

- $80 \text{ GeV} < m_{q\bar{q}} < 160 \text{ GeV}$
- $m_{Z_1, Z_2} > 30 \text{ GeV}$
- $p_{Tee} > 15 \text{ GeV}$ ,
- $p_{T\text{miss}} > 150 \text{ GeV}$
- Selection efficiency: **96%**
- **Total signal efficiency: ~ 68%**

- **Unbiased selection w.r.t.  $\Delta\Phi$**
- Background fully suppressed, but needs additional simulation effort: sample rather small (~1% of the full size), not all flavors contained

# ANGULAR OBSERVABLE $\Delta\Phi$ AND MIXING ANGLE $\Psi_{CP}$

○ Minimum of  $\Delta\Phi$  shifts for non-zero  $\Psi_{CP}$

- Differently from the  $H \rightarrow \tau\tau$  angular observable whose dependence on  $\Psi_{CP}$  can be derived from the differential x-section, here  $\Psi_{CP}$  has to be extracted **empirically**

# HOW TO EXTRACT $\Psi_{CP}$ ?

- ✓ Minimum of  $\Delta\Phi$  is sensitive to  $\Psi_{CP}$ ;
- 1. Determine position of the local minimum (b/a) from experimental (pseudo) data:

$$f(\Delta\Phi, \Psi_{CP}) = A + B \cdot \cos(a \cdot \Delta\Phi - b)$$

- 2. Position (b/a)/  $\Psi_{CP}$  is a linear function of  $\Psi_{CP}$ :

$$(b/a) / \Psi_{CP} = k \cdot \Psi_{CP} + m$$

- 3. Determine from simulation coefficients  $k, m$
- 4.  $\Psi_{CP}$  can be retrieved from quadratic equation:

$$k \cdot \Psi_{CP}^2 + m \cdot \Psi_{CP} - (b/a) = 0$$

## HOW TO EXTRACT $\Psi_{CP}$ ?

✓ Minimum of  $\Delta\Phi$  is sensitive to  $\Psi_{CP}$ ;

1. Determine position of the local minimum (b/a) from experimental (pseudo) data:

$$f(\Delta\Phi, \Psi_{CP}) = A + B \cdot \cos(a \cdot \Delta\Phi - b)$$

2. Position (b/a)/ $\Psi_{CP}$  is a linear function of  $\Psi_{CP}$ :

$$(b/a) / \Psi_{CP} = k \cdot \Psi_{CP} + m$$

3. Determine from simulation coefficients  $k, m$

4.  $\Psi_{CP}$  can be retrieved from quadratic equation:

$$k \cdot \Psi_{CP}^2 + m \cdot \Psi_{CP} - (b/a) = 0$$

## HOW TO EXTRACT $\Psi_{CP}$ ?

- 3. Determine from simulation coefficients  $k, m$
- 4.  $\Psi_{CP}$  can be retrieved from quadratic equation:

$$k \cdot \Psi_{CP}^2 + m \cdot \Psi_{CP} - (b/a) = 0$$

# PSEUDO-EXPERIMENTS

$$\Delta\Psi_{\text{CP}}^{\text{CP}}(\text{stat.}) = 4 \text{ mrad}$$

- 2000 pseudo-experiments give 4 mrad for statistical dissipation of the mean
- Pull distribution indicates that uncertainties are correctly estimated
- Systematic error from the fit parameter uncertainties gives ~1 mrad

# INTERPRETATION

- Common framework is defined in the Snowmass CPV White paper: benchmark parameter  $f_{CP} \sim \sin^2(\Delta\Psi_{CP})$  quantifying relative contribution from CP-odd amplitude
- Interpretation for LHC/HL-LHC and future Higgs factories, for EFT and CP-sensitive observable based measurements

## SUMMARY

- ✓ Complete simulation of CPV Higgs mixing angle ( $\Psi_{\text{CP}}$ ) measurement is performed at 1 TeV ILC with the ILD detector
- ✓ This is the first result in VBF fusion based on angular observable ( $\Delta\Phi$ );
- ✓ Knowing the dependence of  $\Delta\Phi$  minimum to  $\Psi_{\text{CP}}$  from simulation,  $\Psi_{\text{CP}}$  can be determined from (experimental) data;
- ✓ From 8  $\text{ab}^{-1}$  of 1 TeV ILC data, pure scalar state should be measured with 4 mrad statistical uncertainty of  $\Psi_{\text{CP}}$  at 68% CL; Systematic uncertainty from the fit is found to be smaller ( $< 1$  mrad);
- ✓ The above uncertainty corresponds to  $f_{\text{CP}} \approx 1.6 \cdot 10^{-5}$  approaching theoretical target;
- ✓ The study is ongoing in terms of further refinements in background simulation.

**BACKUP**

## ILC AND ILD

- Mature  $e^+e^-$  collider project (TDR in 2013)
- Currently led by the IDT
- Superconducting technology (prototyped for E-XFEL)
- Tunable and upgradeable (1 TeV)
- Comes with numerous options for auxiliary experiments (beam-dump, fixed target)

- Asymptotic transverse momentum resolution =  $2 \cdot 10^{-5} \text{ GeV}^{-1}$
- Jet energy resolution 3-4%
- Impact parameter resolution  $< 5 \mu\text{m}$
- Hermeticity down to 5 mrad
  - Triggerless operation
- Current status summarized in IDR

[arXiv:2003.01116](https://arxiv.org/abs/2003.01116)
