LCTPC Bonn meeting January 2025

Peter Kluit (Nikhef)

# Discuss of two NIM papers on module performance

- First paper with emphasis on module construction and tracking performance (this talk)

Towards a Pixel TPC part I: construction and test of a 32-chip GridPix detector

- Second paper with emphasis particle identification (second talk) and other analysis results (this talk)

Towards a Pixel TPC part II: particle identification with a 32-chip GridPix detector

## Number of hits per chip

Preliminary

- B=0 T has a large Landau tail
- B=1 T smaller Landau tail and a more gaussian distribution
- An electron crossing 8 chips in the module has about 1000 TX3 hits

## Single-electron efficiency of the module

- The single electron efficiency for the quad detector as a function of the grid voltage and the measured ToT  
For the module  $\langle \text{ToT} \rangle = 0.68(0.86) \mu\text{s}$  at  $B = 0(1) \text{ T}$
- The following results were obtained

	$\langle \text{hits} \rangle$ (MOP) <b>B=0</b>	$\langle \text{hits} \rangle$ (MOP) <b>B= 1</b>
Measured	124 (87)	89 (64)
MagBoltz	106	-

Values measured with TPX3 chip at  $V_{th} = 550 \text{ e-}$   
Efficiency curve measured in Ar/C4H10 82/18  
Gain curve measured with test pulses (Kees Ligtenberg)  
8-5-2021

This is consistent with a detector running at 85% single-electron efficiency

## Particle Identification (PID) performance

- The number of hits per unit of track length can be used to identify particles by hit or cluster counting
- Here not only the number of hits or clusters are important but also the fluctuations
- Comparing the number of hits for B=1 T to 0 T one can observe a reduction of the fluctuation
- For a GridPix we know that there is a contribution from UV photons that contribute to the Landau
- The HV scan shows extra hits that are produced

Note the smaller the fluctuations\* the better the PID

\* So if one can reduce the UV photons, using e.g. a double grid it will improve further the PID performance

- Combine chips to form 1 m long track with 60 % coverage for electrons
- **Truncation method:** reject large clusters and then run dEdx @ 90% with slices of 20 pixels along track (xy) (gives nr of selected hits). A large cluster has more than 6 hits in 5 consecutive pixels.
- **Template fit method:** fit the slope of the  $N_{\text{scaled}}$  minimum distance in xy (d) distribution with an exponential function ( $N_{\text{scale}}(d)$ =defines the inverse weights):
 
$$N(d)_{\text{scaled}} = N_{\text{scale}}(d) N_{\text{observed}}(d)$$

$$N(d)_{\text{scaled}} \text{ is then fitted for each track with } N_0 \exp(-\text{slope } d)$$
- Calculate the "PID" variable for electrons and MIP (==70% of hits)
  - Truncation method = nr of selected hits
  - Template fit method = slope
  - Resolution is  $\sigma = \sigma(\text{PID})/\text{PID}$  (for  $\sigma$  we use the rms)

Calculate minimum distance in xy between the hits.

The slope of the distribution is related to the number of primary clusters/cm.

The diffused peak at  $d < 10$  pixels comes from clusters with  $> 1$  hit.

Single chip

Quad module

Figure 5.19: Distribution of distance between hits for a 2.5 GeV electron in pixels from test beam data (blue) and from a Monte Carlo simulation (red).

Thesis Kees Ligtenberg

Peter Kluit (Nikhef)

## Performance of dEdx

### Template fit of slope of the distance distribution

From 10 clusters onwards an exponential distribution is followed.

Below 10 the distribution will be down-weighted ( $N_{\text{scale}}(d) = 1/\text{weight}$ ). The weights are:

Weights B=0 = { 35.0467 , 12.1497 , 4.52914 , 2.76311 , 1.99386 , 1.59795 , 1.3656 , 1.21409 , 1.11898 , 1.04385 };

Weights B=1 = { 22.5617 , 7.39573 , 2.43318 , 1.54528 , 1.23428 , 1.09727 , 1.04368 , 1.01625 , 1.00182 , 0.998178 };

Note the difference in weights in the B=0 and 1 T data sets. This is related to the large Landau fluctuations

## PID performance truncation method

Electron resolution  
3.6%  
1 m track 60% and  
coverage  
Linearity MIP-e = 1.03  
z drift=5-15 mm (flat)

MIP in plot was corrected ...  
thanks Ulli

Peter Kluit (Nikhef)

## PID performance template fit method

Electron resolution  
 2.9%  
 1 m track 60% and  
 coverage  
 Linearity MIP-e = 1.07  
  
 so syst uncertainty on  
 resolution +7%

## PID performance of a Pixel TPC

The dEdx resolution for electrons from data by combining tracks to form a 1 m long track with realistic coverage  $\sim 60\%$  coverage.

Preliminary

Method	B=0 Resolution (%)	B= 1 T Resolution (%)
Truncation	6.0	3.6
Template fit	5.4	2.9

The truncation method has a slightly worse performance – as it is more sensitive to the hits than the template fit method – that is more sensitive to the number of clusters.

## PID Performance extrapolated to the ILD detector

Test beam  $B = 1 \text{ T}$   
 $p = 5,6 \text{ GeV}/c$

Template fit (Truncation)  
electron resolution  
 $2.9 (3.6)\%$

1 m track 60% and  
coverage

## ILD detector

$r_{\text{Inner}} = 329 \text{ mm}$   $r_{\text{Outer}} = 1770 \text{ mm}$

electron resolution =  $2.4 (3.0)\%$   
at  $\theta = \pi/2$

Assume Pixel TPC performance at  
 $B = 1 \text{ T}$  at  $p = 5,6 \text{ GeV}/c$

## ILD dEdx performance

- From dEdx studies in ILD (Ullrich Einhaus)
- Extracted the ILC soft parametrisations for energy loss based on G4 and full simulation of the ILC TPC with T2K gas
- [Link](#) generated in 2020 with ILC soft v02-02 and v02-02-01

## ILD Pixel TPC PID performance

- ILD PID performance is evaluated using the ILD dEdx parametrisation
- For an ILD detector with
  - rInner = 329 mm
  - rOuter = 1770 mm
  - zMax = 2350 mm // half length
- The truncation and template fit method results at B = 1T for the electrons are used as resp. worse and best scenarios
- The performance plots assume  $\cos \theta = 0$  and the PID resolution scales as:
 
$$1/\sqrt{\text{track length} \cdot \langle \text{Eloss} \rangle}$$
- The separation between electrons, kaons, protons and pions is defined as
 
$$|\langle \text{Eloss}_{e,K,p} \rangle - \langle \text{Eloss}_{\pi} \rangle| / \sigma_{\pi}$$

## ILD pixel TPC PID performance

- ILD PID Performance for the two methods: template fit (solid), truncation (dashed)
- The expected pion-**kaon** PID separation for momenta in the range of 2.5-45 GeV/c at  $\cos \theta = 0$  is more than **5.5(4.5) $\sigma$**
- At a momentum of 100 GeV/c the separation is still 3.0(2.0) $\sigma$
- The expected pion-**proton** PID separation for momenta in the range of 2.5-100 GeV/c at  $\cos \theta = 0$  is more than **6.0(4.8) $\sigma$**

# Simulation of ILD TPC with pixel readout

- To study the performance of a large pixelized TPC, the pixel readout was implemented in the full ILD DD4HEP (Geant4) simulation
- Changed the existing TPC pad readout to a pixel readout
- Adapted Kalman filter track reconstruction to pixels

details: PhD [thesis](#)  
Kees Ligtenberg

50 GeV muon track with  
pixel readout

# Performance of a GridPix TPC at ILC

- From full simulation the momentum resolution can be determined
- Momentum resolution is about 15% better for the pixels with realistic coverage (with the quads arranged in modules coverage 59%) and deltas.

## ILD tracking Performance for a Pixel TPC based on test beam

### 10 cm track resolution

Single electron resolution

6 mm track("pad") resolution

Each 10 cm we have a point with a resolution of  $< 18$  ( $31$ )  $\mu\text{m}$  on the track  
 Comparable to performance of a silicon detector (but TPC gas material).

# Performance of a GridPix TPC

## Further integration of the Pixel TPC in the ILD software

A thought by Frank Gaede about combining pixels into pads:

- one could easily project the pixels into pads - of similar/same size as in the current ILD simulation
- but rather than simply adding up the charge, you can compute the true center-of-gravity based position and charge of the virtual pad
- in a second step you combine neighbouring pads to a cluster and compute the position (in  $r$ - $\phi$ ,  $z$ ) of the cluster and create a SimHit from this
- both operations should be linear in time (i.e. one loop over pixels/pads)

This procedure should preserve all the point resolution information of the pixels but allow you to run standard Clupatra as for the pad based TPC reconstruction.

# Pixel TPC: Track fitting at the edge

- In case of the a realistic geometry with detector edges, Kees Ligtenberg observed a worsened momentum resolution and momentum biases. This was traced down to be caused by biases in the residuals at the edge of the detector
- The conclusion was that the track fit should be updated to take into account the (small) biases in the residuals at the detector edge(s)
- Recently, a master student (computational physics) at the UvA, Peter Voerman, has written a track fit that corrects the biases in one pass: "Track fitting at the edge".
- The technique can also be applied to fit hits from other gaseous or non-gaseous detectors:
  - a centre of gravity technique is used (with measured charges over multiple strips near the edge)
  - in case of silicon detector hits near the boundaries of the sensitive volume

- The relative PID resolution for an electron with  $p=5,6$  GeV/c and 1 m track length with 60% coverage is measured to be:
  - 2.9 (3.6)% using the template fit (truncation) methods at  $B = 1$  T
- This is world-best resolution per meter of track length of constructed TPCs running at atmospheric pressure
- The extrapolated PID resolution for the ILD detector is 2.4 (3.0)%
- This allows for particle identification and separation of kaons from pions for momenta 2.5-45 GeV/c at  $\cos \theta = 0$  with more than **5.5 (4.5) $\sigma$** .
- A pixel TPC has become a realistic viable option for experiments
  - High precision tracking like ILD@ILC in the transverse and longitudinal planes,  $dE/dx$  by electron and cluster counting, excellent two track resolution, digital readout that can deal with high rates

## ILD Pixel TPC PID performance

- Separation pion-kaon for different  $\cos(\theta)$  values due to the track length dependence
- For  $\cos(\theta)=0$  till 0.95 the separation lies between the black and red curves. Only above 0.95-0.975 the separation drops till the blue curve.
- Excellent performance over very large polar angle range

- ▶ Close to the edge of a detector, measurements of the particle's position are biased, leading to biased track parameters during track fitting
- ▶ The bias in the measurements can be described by this equation:

$$c = \begin{cases} 0 & \text{if } x < p_1 \\ \frac{(x-p_1)^2}{p_0} & \text{if } p_1 < x < p_2 \\ \frac{2(p_2-p_1)(x-p_2)}{p_0} + \frac{(p_2-p_1)^2}{p_0} & \text{if } p_2 < x \end{cases} \quad (1)$$

- ▶  $p_0$ ,  $p_1$  and  $p_2$  are dependent on the amount of diffusion in the detector and the detector geometry

- ▶ The fit is done by minimizing the following  $\chi^2$ :

$$\chi^2 = \sum_{i=1}^N \frac{(\sin(\phi)(x_{m,i} - c_i) - \cos(\phi)y_{m,i} - d_0)^2}{\sigma_i^2} \quad (2)$$

- ▶ Without correction,  $c_i = 0$
- ▶ With correction,  $c_i$  is calculated using equation 1
- ▶ As seen in the figures, this correction significantly reduces the bias in the fitted parameters as the fraction of measurements close to the edge increases

# Operation of a Pixel TPC at CEPC or FCC-ee

# A Pixel TPC at CEPC or FCC-ee

The most difficult situation for a TPC is running at the Z.

At the Z pole with  $L = 200 \cdot 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$  Z bosons will be produced at  $\sim 60 \text{ kHz}$

Picture IHEP

## ■ Can a pixel TPC reconstruct the events?

- The TPC total drift time is about  $30 \mu\text{s}$
- This means that there is on average 2 event / TPC readout cycle
- YES: The excellent time resolution: time stamping of tracks  $< 1.2 \text{ ns}$  allows to resolve and reconstruct the events

## ■ Can the current readout deal with the rate?

- Link speed of Timepix3 (in Quad):  $2.6 \text{ MHits/s}$  per  $1.41 \times 1.41 \text{ cm}^2$  Testbeam up to 1.5 kHz
- YES: This is sufficient to deal with hits from Z's in high luminosity Z running
- NB: Data size is not a show stopper as e.g. LHCb experiment shows using the VeloPix chip

# A Pixel TPC at CEPC or FCC-ee

## ■ What is the current power consumption?

- No power pulsing possible at these colliders (at ILC power pulsing was possible)
- Current power consumption TPX3 chip  $\sim 2\text{W}/\text{chip}$  per  $1.41 \times 1.41 \text{ cm}^2$
- So: good cooling is important but in my opinion no show stopper
- For Silicon detectors lower consumption for the chips and cooling is an important point that needs R&D (e.g. microchannel cooling).
- To save power the TPX3/4 chips can be run in LowPowerMode: **reduction factor 10.**

## ■ Can one limit the track distortions?

- There are two important sources of track distortions:
  - the distortions of the TPC drift field due to the primary ions
  - the distortions of the TPC drift field due to the ion back flow (IBF)
- At the ILC gating is possible; for CEPC or FCC-ee this is more involved, for a Pixel TPC a double grid is the best solution (see next slide)

# A Pixel TPC at CEPC or FCC-ee

- **Is it possible to reduce the IBF for a pixel TPC?**
  - IDEA: by making chip with a double grid structure (see back up slide)
  - This idea was already realized as a TWINGRID NIMA 610 (2009) 644-648
  - For GEMs for the ALICE TPC this was also the way – several GEMs on top of each other to reduce IBF
  - For the Pixel the IBF can be easily modelled and with a hole size of 25  $\mu\text{m}$  an IBF of  $3 \cdot 10^{-4}$  can be achieved and the value for  $\text{IBF} \cdot \text{Gain} (2000)$  would be 0.6.
  - YES: the IBF can be reduced to 0.6 but this needs R&D
  - In the new detector lab in Bonn it is possible to make and study this device
- **What would be the size of the TPC distortions?**
  - Tera-Z studies by Daniel Jeans and Keisuke Fuji show that for FCC-ee or CEPC this means: distortions from Z decays up to  $< O(100) \mu\text{m}$
  - Beam strahlung gives (now) a factor 200 more hits in the TPC. See Daniel Jeans studies in ECFA2024. Detector optimization and shielding is important for TPC and Silicon detectors to reduce pair background. A recent study shows the potential.
  - It was argued that in an ILD like detector the distortions can be mapped or fitted out using the VTX-SIT/SET detectors (see next slide).

# Fitting out TPC distortions in ILD/CEPC

- It is possible to map out distortions using e.g. muons from Z decays
  - E.g. by fitting the 3D spatial distribution as a function of time as was done by ALEPH and more recently by ALICE. Using this distribution the hits positions are corrected and the TPC track refitted.
- However, with silicon trackers around the TPC, more elaborate methods can be used. One can use the track predictions based of the silicon trackers SIT and SET to correct on a track-by-track level the TPC track.
  - One can use as a constraint that the extrapolated positions and angles agree with the measured in the SIT and SET.
  - Practically, one can e.g. correct the TPC track parameters
- The ultimate way is a fitting technique similar to ATLAS. In the ATLAS track fit the common systematics is fitted out for sets of Muon hits. For ILD/CEPC the fit would fit free parameters in the distortion model, while using as a constraint the SIT and SET position and direction measurements.
  - The simplest case is a model where the strength (amplitude) and radial dependence would be scaled and a model is used for the 3D extrapolations.

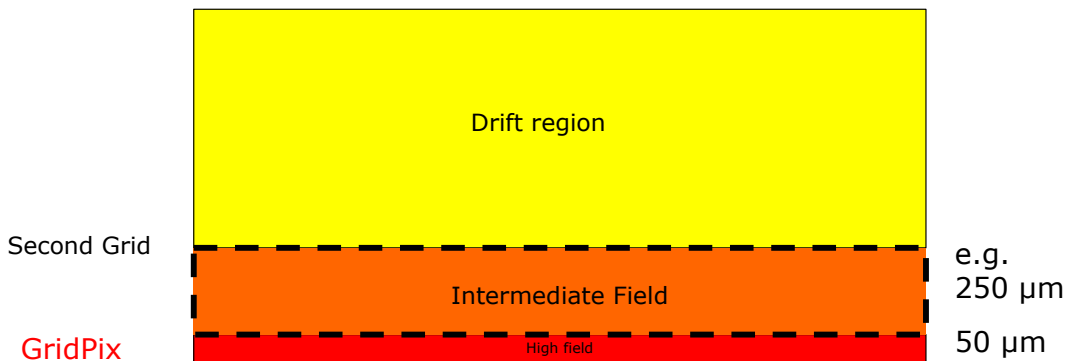

# Conclusions: Pixel TPC at CEPC or FCCee

- YES: a pixel TPC can reconstruct the Z events in one readout cycle
- YES: the current **readout** of the Timepix3 chip can deal with the Z hit rate running
  - The beam-beam background currently dominates the hit rate
- The current **power consumption** is  $1\text{W}/\text{cm}^2$ . By running the TPX chips in low power mode this can be reduced by a factor of **10**. Still good **cooling** is important no show stopper.
- Track distortions in the TPC drift volume are a concern at high lumi Z running:
  - Track distortions from Z decays in TPC are  $O(100)\ \mu\text{m}$
  - The current MDI design FCCee/CEPC gives a lot of beam-beam background more than a factor 100 more hits from the beam than from the Z. **An improved MDI is needed. Also a high B field (say 3 T) would help (now an option at FCCee).**
  - It is possible to reduce the IBF for a pixel TPC by making a device with a **double grid**
  - A double grid needs dedicated R&D that can be performed in the new lab in Bonn
- The Z physics program at FCC-ee or CEPC with an ILD-like detector with a Pixel TPC (with double grid structures) sliced between two silicon trackers (VTX-SIT and SET) can be fully exploited. The reduction of beamstrahlung by an improved MDI – and the fitting out of distortions - needs more study.
- A pixel TPC can perfectly run at WW, ZH or tt energies where track distortions are several orders of magnitude smaller

# Reducing the Ion back flow in a Pixel TPC

The Ion back flow can be reduced by adding a second grid to the device. It is important that the holes of the grids are aligned. The Ion back flow is a function of the geometry and electric fields. Detailed simulations – validated by data – have been presented in [LCTPC WP #326](#).

With a hole size of 25  $\mu\text{m}$  an IBF of  $3 \cdot 10^{-4}$  can be achieved and the value for IBF\*Gain (2000) would be 0.6.

Ion backflow	Hole 30 $\mu\text{m}$	Hole 25 $\mu\text{m}$	Hole 20 $\mu\text{m}$
Top grid	2.2%	1.2%	0.7%
GridPix	5.5%	2.8%	1.7%
Total	$12 \cdot 10^{-4}$	$3 \cdot 10^{-4}$	$1 \cdot 10^{-4}$
transparancy	100%	99.4%	91.7%
