

# Optimization of Guinea-Pig grid for ILC feedback simulations

Maria del Carmen Alabau, Philip Bambade, Guy Le Meur

29th March 2007

1

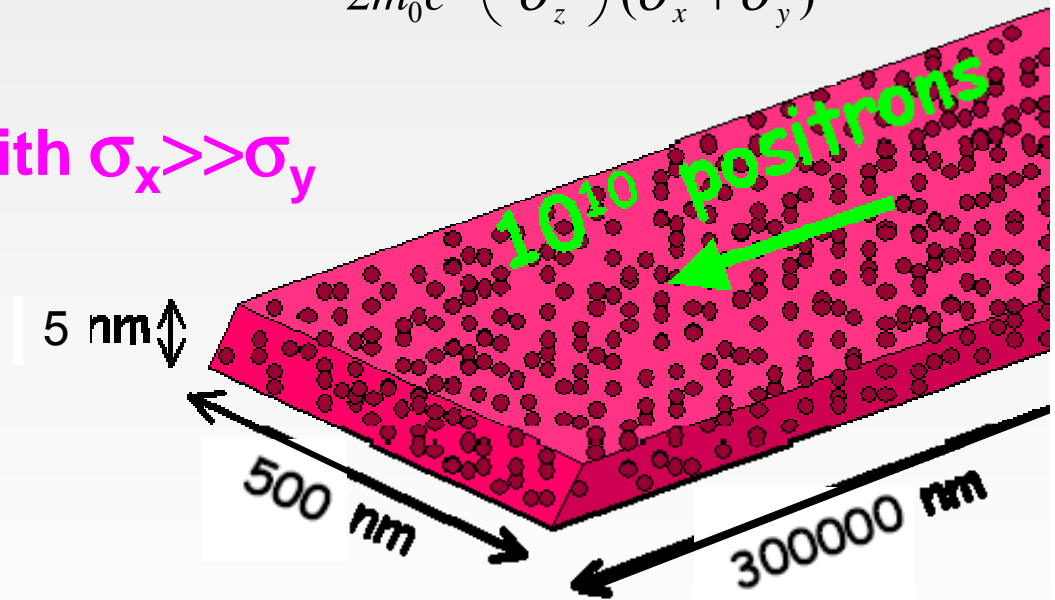

# The luminosity issue: flat beams

To maximise the luminosity need to make  $\sigma_x \sigma_y$  small  $L = \frac{\eta_{RF} P_{RF} N}{4\pi \sigma_x \sigma_y E_{cm}} H_D$

BUT keep  $(\sigma_x + \sigma_y)$  large to reduce  $\delta_B$   $\delta_B \approx 0.86 \frac{er_e^3}{2m_0 c^2} \left( \frac{E_{cm}}{\sigma_z} \right) \frac{N^2}{(\sigma_x^2 + \sigma_y^2)}$

Trick: use “flat beams” with  $\sigma_x \gg \sigma_y$

Very sensitive to small vertical offsets

Need to maintain the beams aligned at the IP with  $\sim 0.5$  nm precision !

# Beam-beam deflection

Beam-beam interaction focuses (defocuses) the beams.

In addition, if there is an offset between the beams, there is a net force that deflects the trajectories.

out-going angle is the main signal for the IP position feedback system

deflection angle for  $|y_0| \ll \sigma_y$

$$y' = -\frac{2Nr_e}{\gamma \sigma_{x,y} (\sigma_x + \sigma_y)} \frac{y_0}{f_y} = -\frac{y_0}{f_y}$$

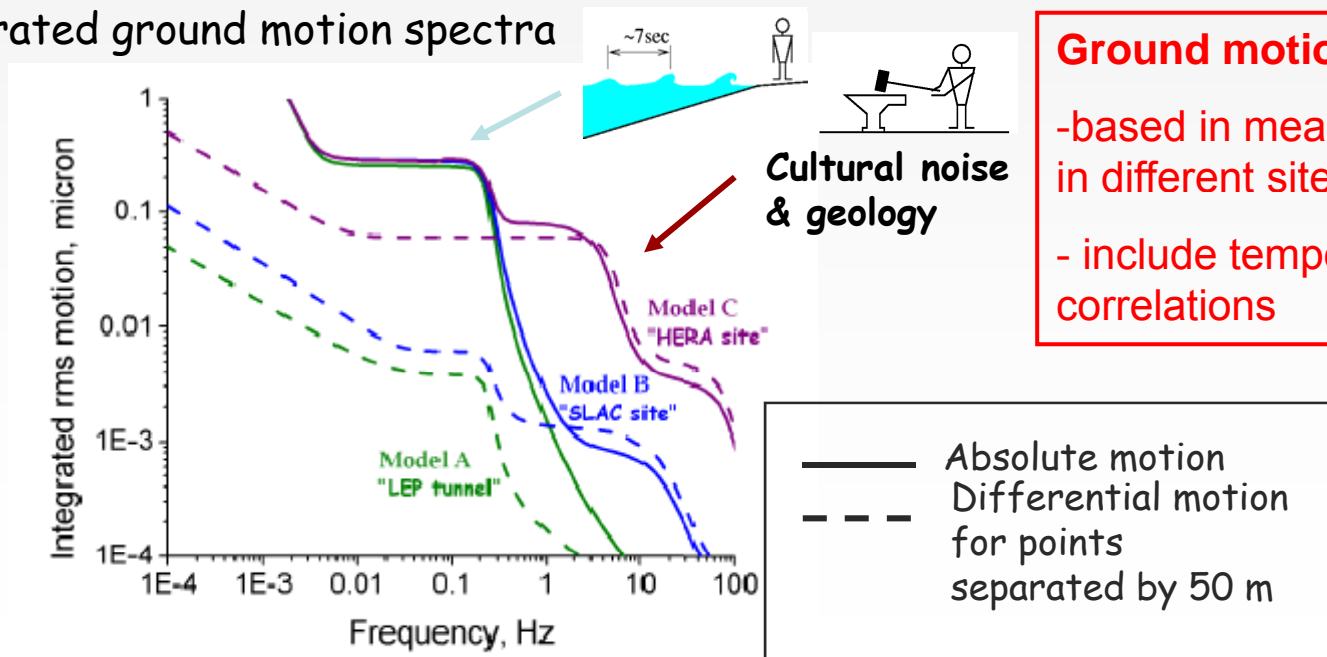

# Sources of magnet displacements

Magnet displacements introduce offsets at the IP

Source of magnet displacements: ground motion

Integrated ground motion spectra

**Ground motion models:**

- based in measurements taken in different sites
- include temporal and spatial correlations

\* See e.g. A. Seryi, Ground Motion and Vibration Issues for Accelerators, Proceedings of the 2001 PAC, Chicago

# Beam-based IP position Feedback Simulation

Amplitudes of the IP y-offsets:

Train frequency:  
~ hundreds of nm

Bunch-to-bunch frequency:  
~ fraction of  $\sigma_y$

Structure of the beam:

## Beam-beam deflection IP position feedback system

1. Measure the out-going angle

2. Predict the offset between the beams

3. Correct the next bunch

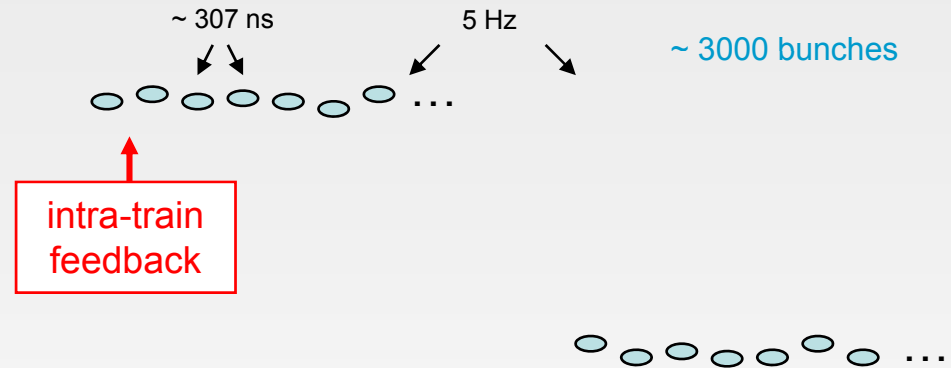

# Beam-based IP position Feedback Simulation

Amplitudes of the IP y-offsets:

Train frequency:  
~ hundreds of nm

Bunch-to-bunch frequency:  
~ fraction of  $\sigma_y$

Structure of the beam:

## Beam-beam deflection IP position feedback system

1. Measure the out-going angle

2. Predict the offset between the beams

3. Correct the next bunch

# Beam-Beam Feedback Simulation with Realistic Errors in the BDS (1)

Beam-based IP position feedback simulation using the code PLACET:

- Misalignment of the elements of the BDS applying ground motion model B\* every 0.2 seconds, for each train (without misalignment inside a train)
- Simulations for successive time intervals of ground motion applied
- Track the beam through the BDS
- Collision with GUINEA-PIG to obtain the outgoing angle used for the correction
- Correct the beam position with the kicker located just after the final doublet

**repeat bunch-to-bunch**

\* See e.g. A. Seryi, Ground Motion and Vibration Issues for Accelerators, Proceedings of the 2001 PAC, Chicago

# Beam-Beam Feedback Simulation with Realistic Errors in the BDS (2)

Effect of the ground motion in the lattice elements:

Misalignment of the elements with ground motion model B (50 seeds)  
(ground motion applied at successive time intervals)

Misalignment difference of each element in the  $e^-$  line respect to the same element in the  $e^+$  one

Addition of the misalignment of each element in both lines

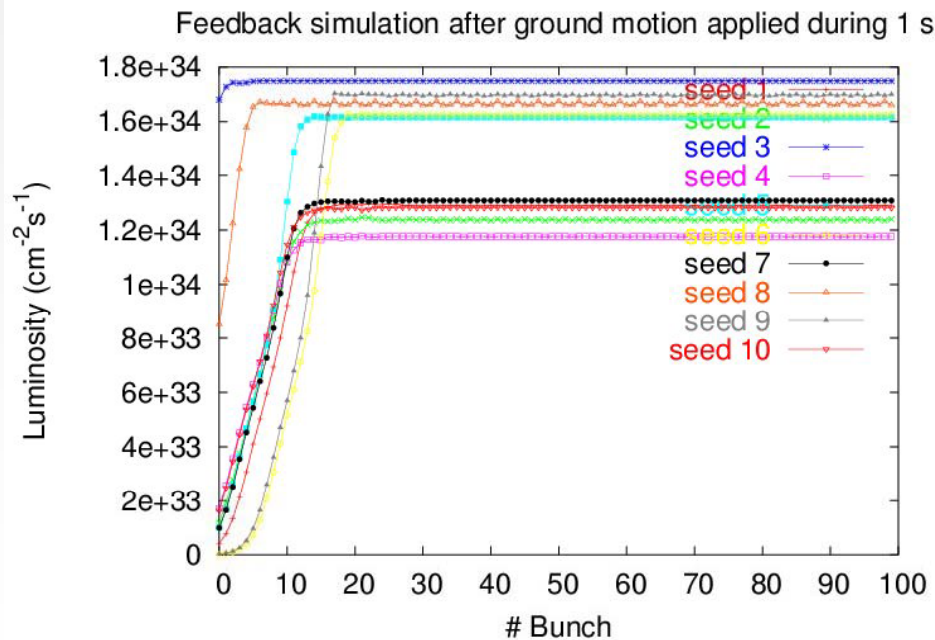

# Beam-Beam Feedback Simulation with Realistic Errors in the BDS (3)

Feedback response:

Feedback simulation with ~50 seeds after ground motion applied during 1second

$e^+e^-$

$e^-e^-$

Feedback simulation for ground motion during different time intervals 9

# Beam-Beam Feedback Simulation with Realistic Errors in the BDS (4)

Feedback simulation after ground motion applied during different time intervals:  
(average luminosity for ~50 seeds)

$e^+e^-$

$e^-e^-$

Correction for the  $e^-e^-$  mode is slower compared with  $e^+e^-$ , but the average luminosity over a full train can be recovered

# Beam-Beam Feedback Simulation with Realistic Errors in the BDS (5)

Feedback simulation done for:

- e<sup>+</sup>e<sup>-</sup> and e<sup>-</sup>e<sup>-</sup>
- ~8 different successive time intervals of ground motion
- 50 seeds each lattice misalignment

Correction done bunch-to-bunch for 200 bunches:  
200 collisions simulated with Guinea-Pig

Total: the order of 100000 collision simulations

## Beam-Beam Feedback Simulation with Realistic Errors in the BDS (5)

Correction done bunch-to-bunch for 200 bunches:

200 collisions simulated with Guinea-Pig

if 1 min / collision  $\Rightarrow$  ~ 8 h

if 3 min / collision  $\Rightarrow$  ~ 24 h

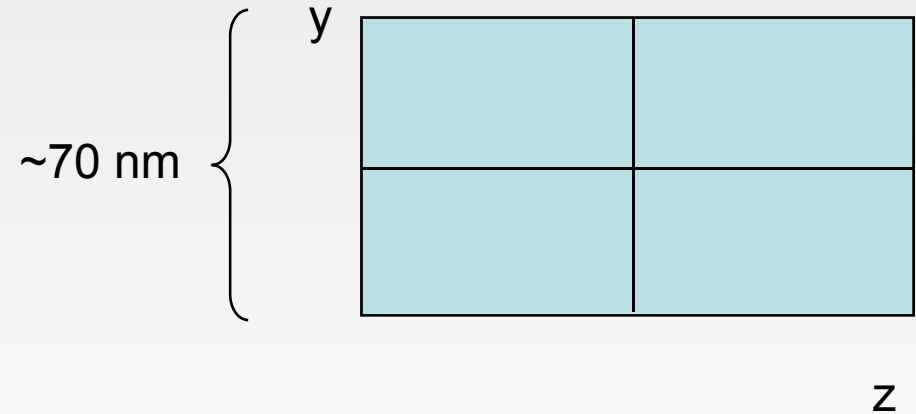

Time depends on size and precision grid:  
Need to optimize the grid according to the offset between the beams

# Guinea-Pig grid

## Grid parameters for 0 nm offset (e+e-)

Size of the grid (half of the grid)

```
cut_x = 3 * sigma_x.1  
cut_y = 6 * sigma_y.1  
cut_z = 3 * sigma_z.1
```

Number of cells

```
n_x = 32  
n_y = 128  
n_z = 24
```

70 nm / 128 cells:

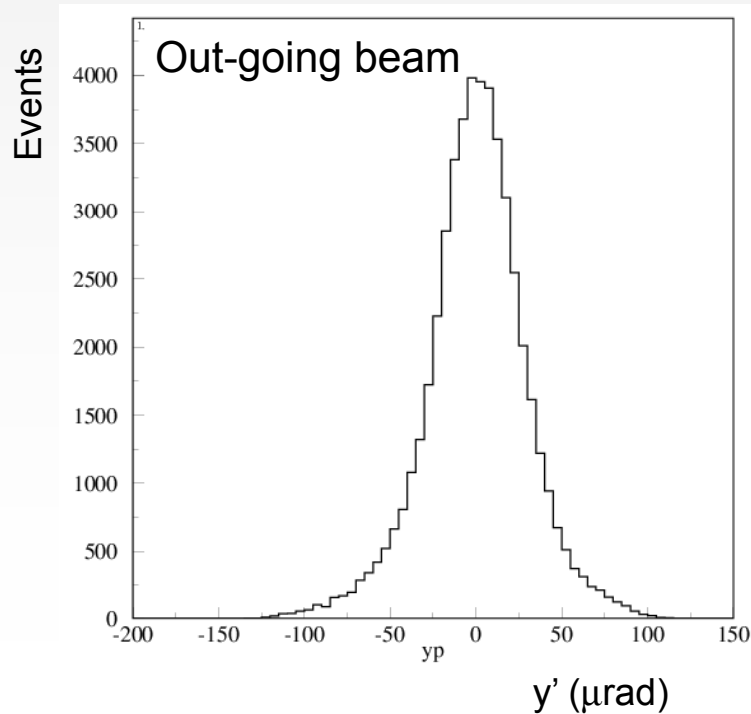

$\text{size\_cell}(y) \sim (1/10) \sigma_y$

# Guinea-Pig grid

## Grid parameters for 0 nm offset (e+e-)

Size of the grid (half of the grid)

$$\begin{aligned} \text{cut}_x &= 3 * \sigma_{x.1} \\ \text{cut}_y &= 6 * \sigma_{y.1} \\ \text{cut}_z &= 3 * \sigma_{z.1} \end{aligned}$$

# Guinea-Pig grid

Grid parameters for vertical offset between the beams:

200 nm vertical offset (e+e-)

disruption

average kick

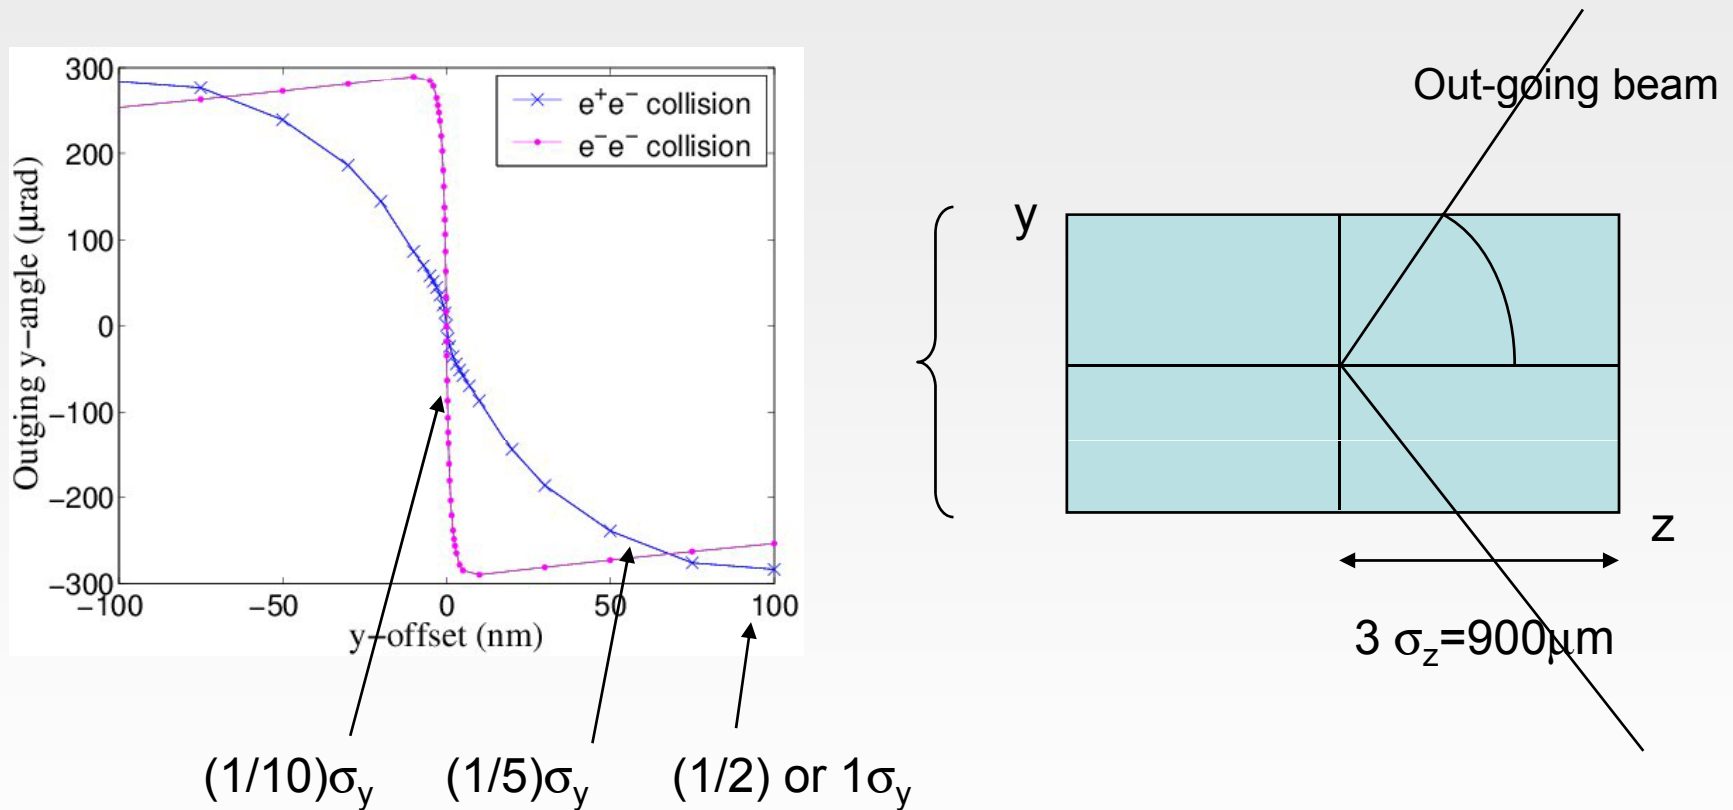

deflection curve

- Increase  $y$  grid size
- Increase the cell size

# Guinea-Pig grid

Grid parameters for vertical offset between the beams:

- Increase the cell size
- Increase y grid size: to loose maximum ~1% of the particles

# Guinea-Pig grid

Grid parameters for e-e- collisions: need more time

0 nm vertical offset (e-e-)

disruption

Disrupted angle 8 times the e+e- one:

Vertical grid size 8 times the e+e- one

$$\begin{aligned} \text{cut}_x &= 3 * \text{sigma}_x.1 \\ \text{cut}_y &= 48 * \text{sigma}_y.1 \\ \text{cut}_z &= 3 * \text{sigma}_z.1 \end{aligned}$$

To maintain the same precision:

Number of cells x 8

$$\begin{aligned} n_x &= 32 \\ n_y &= 1024 \\ n_z &= 24 \end{aligned}$$
