# Two Bugs Found

---

- ◆ Occasionally, tracks found with momentum/charge opposite MC particle
  - Reflects CP symmetry in equations of motion for a charged particle
  - Seedtracker resolves this symmetry by ordering hits in  $|z|$  and having the track move from small  $|z|$  to large  $|z|$
  - Algorithm was being fooled when a hit was added to the track that was “behind” the DCA giving a negative path length from the DCA to the hit
  - Bug fixed by failing fits if there are hits with negative path length
- ◆ Occasionally would have two tracks sharing  $>1$  hit
  - Merging algorithm chooses between track candidates that share  $> 1$  hit, keeping the candidate with the most hits / best  $\chi^2$
  - Merging algorithm only dealt with first track with shared hits due to some “fuzzy logic”
  - Fixed so that merging is done with all track candidates (adding one new track can now delete two or more lower ranked tracks)
- ◆ Thanks to Ron for spotting these problems!

# Reconstruction Driver

---

- ◆ Reconstruction driver produced for SiD02

- Can be found at:

[org.lcsim.recon\\_tracking\\_seedtracker.ReconTracking.SiD02ReconTrackingDriver](https://github.com/lcsim/recon_tracking_seedtracker.ReconTracking.SiD02ReconTrackingDriver)

- ◆ Strategies generated using 10K ttbar events

- ◆ Uses virtual segmentation for both pixel and strip hits

- Option exists to run with FullCCDSimulation for pixel detectors
- Strategies built for FullCCDSimulation (includes inefficiency in pixel layers)
- Ran out of time to properly test tracking with FullCCDSimulation

- ◆ Treats forward tracker disks as pixels

- Only significant difference from SiD01

# Efficiency vs $p_T$

# Efficiency vs $\theta$

# Purity

# Mis-Measured Tracks
