Outline

- 1 Optimal Flat Conversion Target
 - General Considerations
 - Target for Polarized Positrons
- 2 Rod Conversion Target
 - Idea and Estimations
 - Sliced Rod Scaling
 - Example of Rod
- 3 Summary
 - Summary
 - Backup slides
 - Acknowledgement

Fates of Gammas and Positrons

L target thickness, κ positron production, λ positron losses

- Balance of gammas
 - $\exp(-\kappa L)$ gammas pass through target
 - $1 - \exp(-\kappa L)$ gammas convert into positron–electron pairs
- Balance of positrons
 - Total production $1 - \exp(-\kappa L)$
 - $(1 + \lambda/\kappa) [1 - \exp(-\kappa L)] - \lambda L$ escape from target
 - Fraction with $E_{ac} \leq E \leq E_{max}$ accepted

For each spectrum of gammas, the target material (κ, λ) , and the threshold accepted positrons energy E_{ac} there exists the optimal target thickness with maximal yield of positrons

Transformation of Laser Photons into Positrons

Source spectra for preselection 0.5

Thick-target spectra for preselection 0.75

Optimal Target Thickness

Higher the polarization thinner the target, smaller the yield

Compton spectra, $E_{\gamma}^{\max} = 20 \text{ MeV}$

Validation of the Model (A. Schalicke, S. Riemann)

Dependence on the target thickness, Ti and W

Maximal yield and polarization

Envelopes for Ti and W targets
(optimal thickness)

Dash curve: a rod target

- Polarization degree up to 0.7–0.8 attainable at yield ≥ 0.001 per scattered laser photon
- Higher the polarization:
 - lower the yield
 - higher the quality of positron beam (smaller energy spread, emittance)
 - thinner the conversion target, lower the power load
- High- Z material more effective (T. Omori, 2007)

Rod Conversion Target

Idea: V.Lapko, N.Shulga (2007): *positrons path shorter than gammas*

b, d – spacing and disk thickness
(in units of disk radius)

- Path length of positrons much shorter than of gammas
- Increased yield of positrons due to reduced losses
- Decreased target heat load
- Longer target (in rad. length) may be employed

Density and Emittance

Disk spacing $b = 1$, initial angular spread $r'_0 = 0.1$)

Cylindrical coordinate frame

Density profile after source and consecutive scattering disks

Halo distribution over the radial phase plane after first disk

Stretching of Rod

$E_{\text{positron}} = 15 \text{ MeV}$, $r = 1 \text{ r.l.}$, $d = 0.01 \text{ r.l.}$

Path length of escaped e^+ vs. spacing

Ratio of escaped e^+ vs. spacing

Scaling (not accounted for energy decrease): $b\sqrt{\langle r^2 \rangle} \sim b\sqrt{d}/\gamma$ (d in r.l. units) – increase in energy of positrons is compensated with increase of disk spacing.

A Rod Conversion Target – Example

$$E_{\gamma}^{(\max)} = 20 \text{ MeV}, \quad E_{\text{pos}} = (10 \dots 20) \text{ MeV}$$

- Rod parameters

- material: tungsten
- total thickness: 3 r.l.
(flat target opt. 0.52 r.l.)
- radius: 1 r.l. (3.3 mm)
- disk thickness: 0.01 r.l.
(33 μm)
- spacing: $b = 0.3, 1$ (length
1 m, 3 m)

- Positrons

- produced per scattered
gamma: 0.26
- produced per income
gamma: 0.52
- escaped per scattered:
0.07, 0.13 for $b = 0.3, 1$ resp
(comp. 0.01 for flat target)
- instant emittance (source):
 $\approx 10 \mu\text{m rad}$ ($b = 1$)
- polarization: 0.6

Optimal Flat Target

Compton sources

- Optimal target thickness scaled as E_{\max} of gammas
- Polarization degree of positrons determined by postselection
- Higher the polarization:
 - thinner the optimal target
 - smaller the positron intensity
 - higher the positron beam quality – smaller emittance and energy spread

Polarization degree up to 0.7–0.8 attainable at yield ≥ 0.001 per scattered laser photon in Compton sources

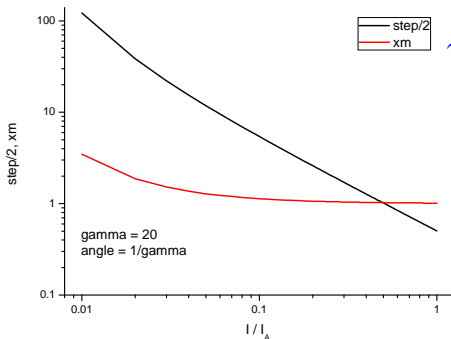

Rod Target

- The rod converter is more effective than the optimal target
- It has no optimal integral thickness and length:
the longer the more effective
- Dimensions of the sliced rod depend of the experimental setup
- Collection of positrons is of prime importance

The rod converter might be applied in the sources other than Comptons: conventional, hybrid,

Collection of Positrons

Option – current along rod (*imitation of “lithium lens”*)

- Trajectory of positron determined by
 - rod current, and emitting angle
 - energy of positrons,
 - and emitting angle.
- Trajectory of positron scaled as rod radius

Max off-axis deviation and half-step vs. current ($I_A = 17 \text{ kA}$)

Thank You

Thank you for your attention and patience
