– Physics Benchmarks for the ILC Detectors

**Goal = 30% /  $\sqrt{E_{jet}}$**

← Key: Calorimeter

Particle Flow Algorithm

# Why do we need PFA for ILC

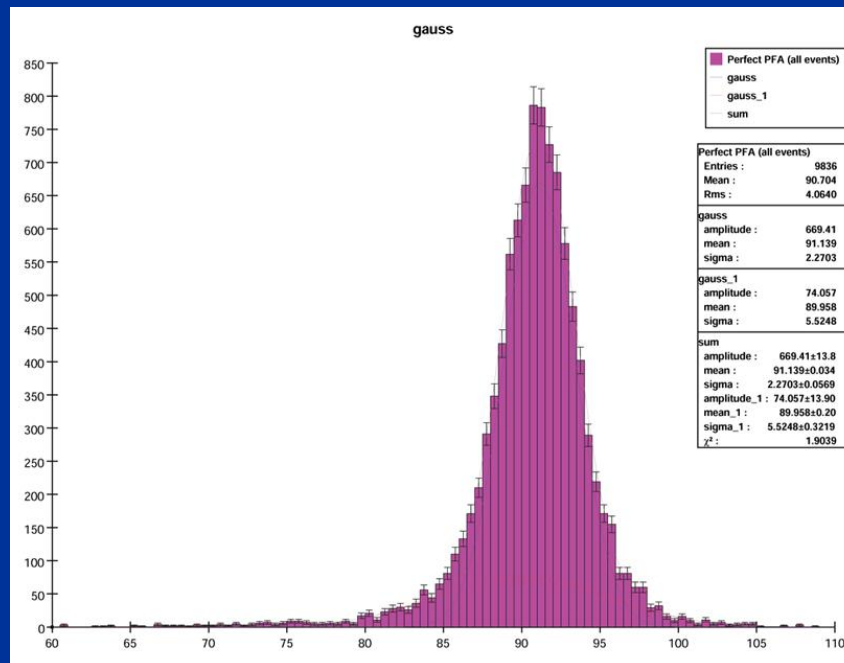

- Measure jets in the PFA way...

| Particles in Jets | Fraction of jet energy | Measured with                    |
|-------------------|------------------------|----------------------------------|
| Charged           | 65%                    | Tracker, negligible uncertainty  |
| Photon            | 25%                    | ECal, 15%/ $\sqrt{E}$            |
| Neutral hadron    | 10%                    | ECal + HCal, ~50-60%/ $\sqrt{E}$ |

- **Clear separation of the 3 parts is the key issue of PFA**
  - Charged particle, photon and neutral hadron: all deposit their energy in the calorimeters
  - **Maximum segmentation** of the calorimeters is needed to make the separation possible
- One Major R&D issue: development of PFA
  - Meets the ILC goal for jet energy resolution
  - Can be used for detector optimization
- Argonne has two parallel efforts on PFA development

# Perfect PFA: NO algorithm effect

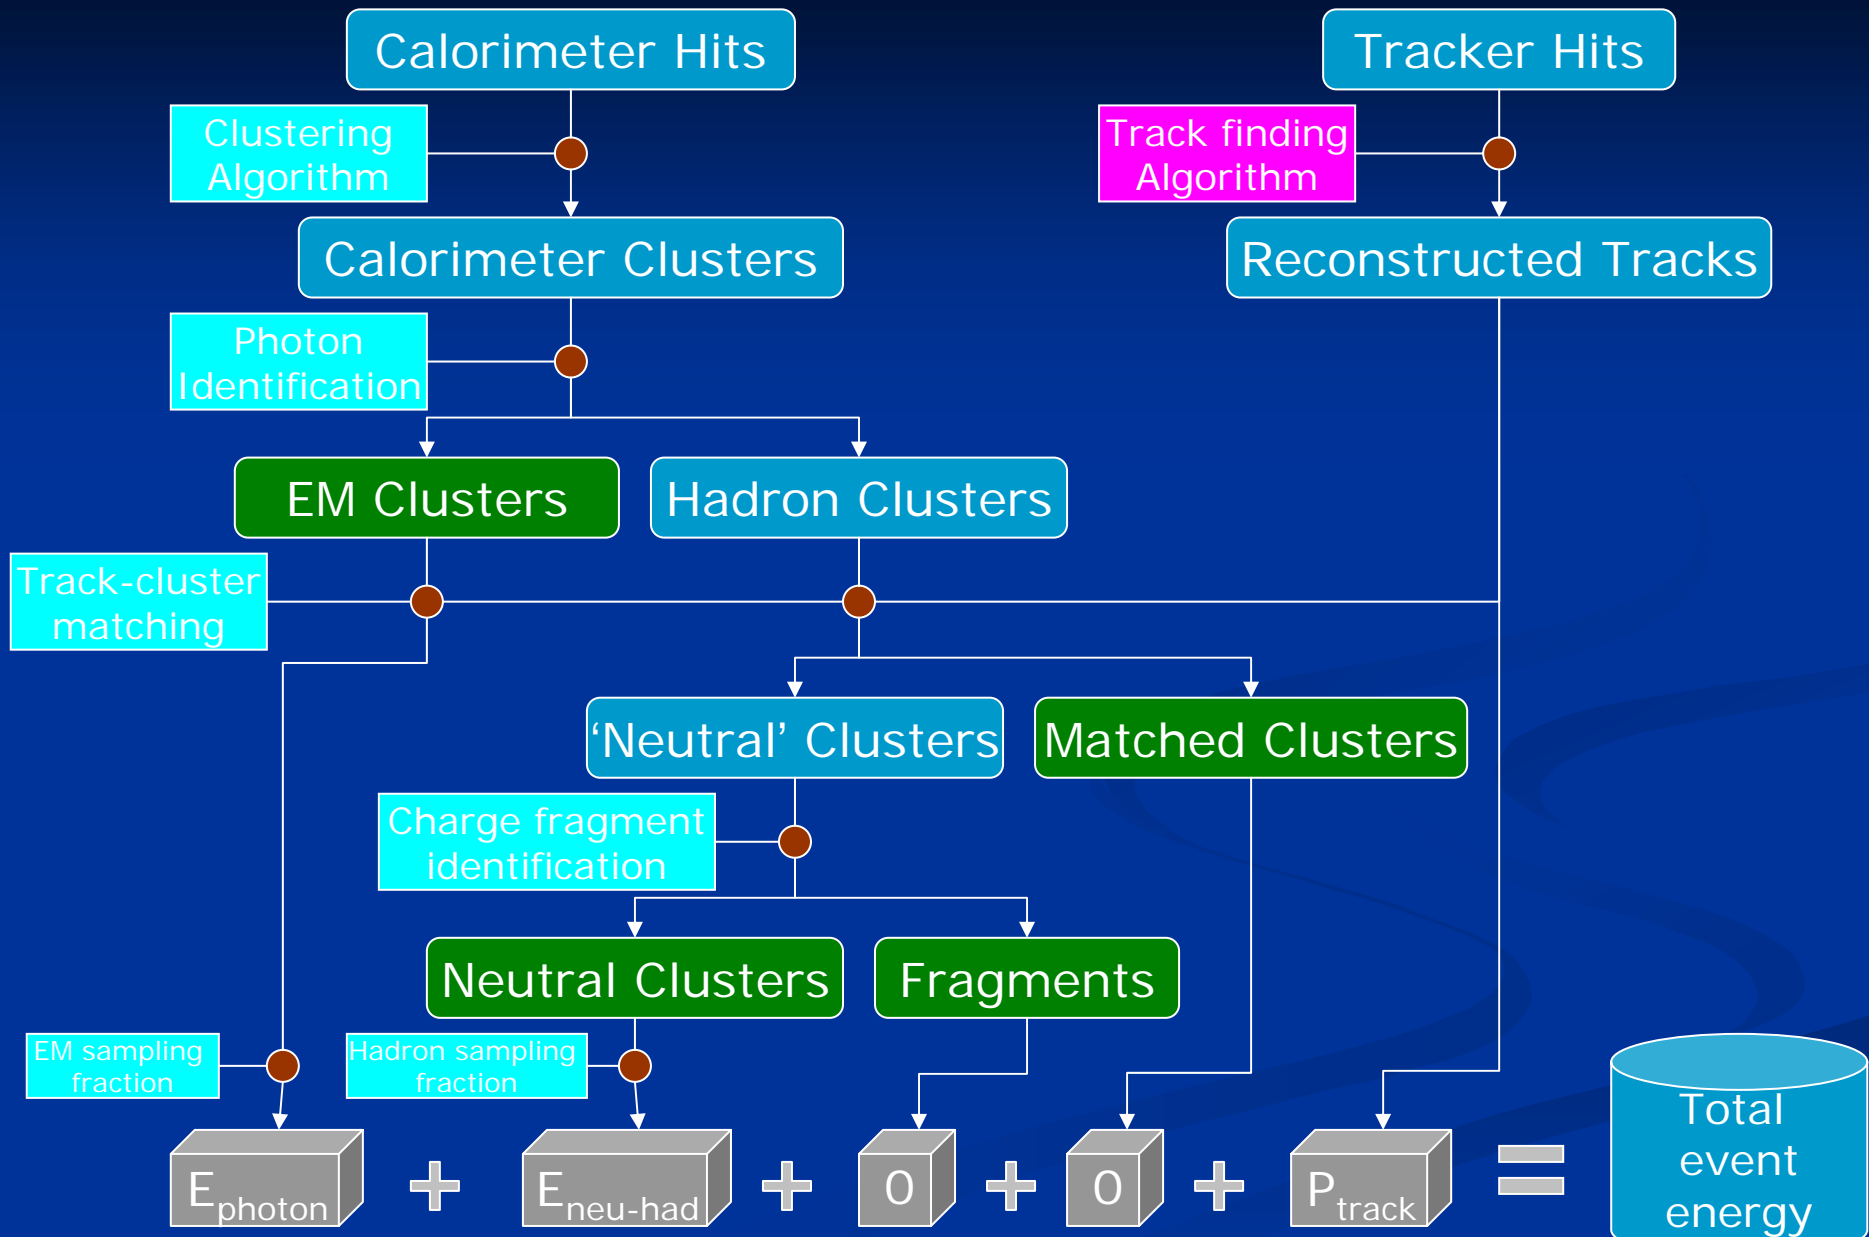

- Take MC track momentum as the energy of charged particles
- Remove calorimeter hits associated with charged particles
- Sum up everything else in the calorimeter as neutral energy
  - Apply appropriate sampling fractions for photon hits and neutral hadron hits
- Z-pole events, no jet algorithm applied

Example: SiD aug05\_np

central peak  
~2.3 GeV  
(no event selection)

# PFA effort: overview

# Clustering algorithm: hit density

$$D_i = \sum_{\{j \neq i\}} (e^{-\frac{(\vec{V}_1 \cdot \vec{R}_{ij})}{|\vec{V}_1|^2}} \times e^{-\frac{(\vec{V}_2 \cdot \vec{R}_{ij})}{|\vec{V}_2|^2}} \times e^{-\frac{(\vec{V}_3 \cdot \vec{R}_{ij})}{|\vec{V}_3|^2}})$$

With  $V_3 = V_f$  (if  $(V_f \cdot R_{ij}) > 0$ ) or  $V_b$  (if  $(V_b \cdot R_{ij}) > 0$ )

- Hit density reflects the closeness from one hit  $i$  to a group of hits  $\{j\}$ 
  - $\{j\} = \{\text{all calorimeter hits}\}$  to decide if hit  $i$  should be a cluster seed
  - $\{j\} = \{\text{all hits in a cluster}\}$  to decide if hit  $i$  should be attached to this cluster
- Consider cell density variation by normalizing distance to local cell separation
  - Density calculation takes care of the detector geometry
  - Clustering algorithm then treat all calorimeter hits in the same way

# Clustering algorithm: grow a cluster

- Find a cluster seed: hit with highest density among remaining hits
- Attach nearby hits to a seed to form a small cluster
- Attach additional hits based on density calculation
  - $i$  = hit been considered,  $\{j\}$  = {existing hits in this cluster}
  - EM hits,  $D_i > 0.01$
  - HAD hits,  $D_i > 0.001$
  - Grow the cluster until no hits can be attached to it
- Find next cluster seed, until run out of hits

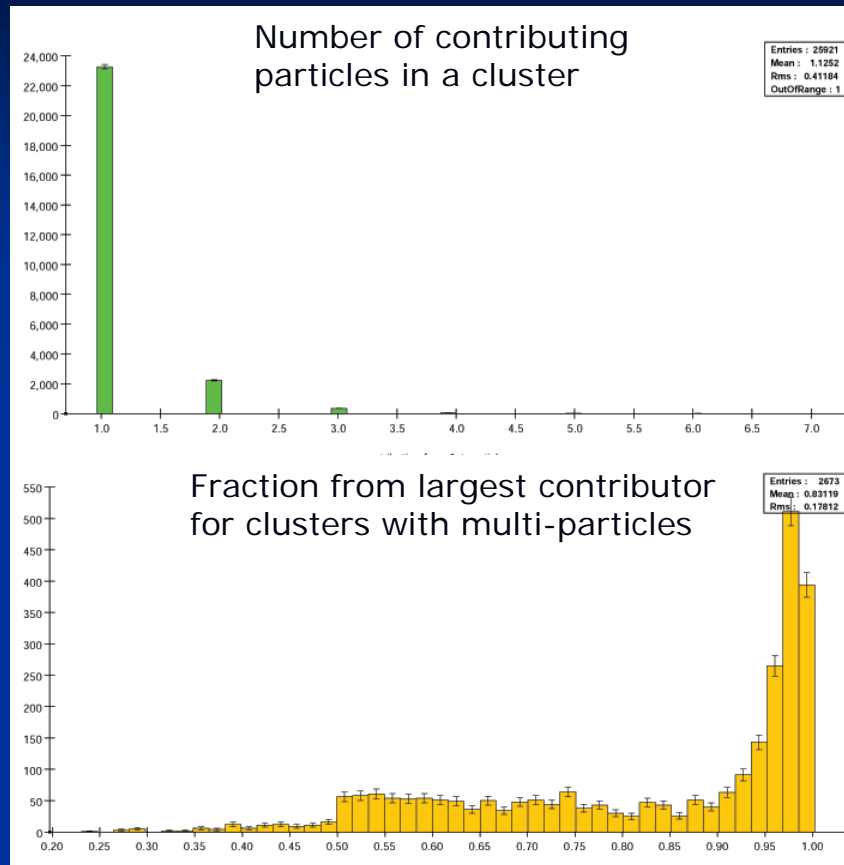

# Density driven clustering

| Particle        | ECal hit efficiency | HCal hit efficiency | Overall hit efficiency | Overall energy efficiency |
|-----------------|---------------------|---------------------|------------------------|---------------------------|
| Photon (1GeV)   | 89%                 | 43%                 | 89%                    | 91%                       |
| Photon (5GeV)   | 92%                 | 54%                 | 92%                    | 96%                       |
| Photon (10GeV)  | 92%                 | 61%                 | 92%                    | 97%                       |
| Photon (100GeV) | 95%                 | 82%                 | 95%                    | >99%                      |
| Pion (2 GeV)    | 78%                 | 59%                 | 75%                    | 71%                       |
| Pion (5 GeV)    | 81%                 | 70%                 | 79%                    | 80%                       |
| Pion (10GeV)    | 84%                 | 80%                 | 83%                    | 85%                       |
| Pion (20GeV)    | 85%                 | 87%                 | 88%                    | 91%                       |

- Typical electron cluster energy resolution  $\sim 21\%/\sqrt{E}$
- Typical pion cluster energy resolution  $\sim 70\%/\sqrt{E}$
- All numbers are for one main cluster (no other fragments are included)

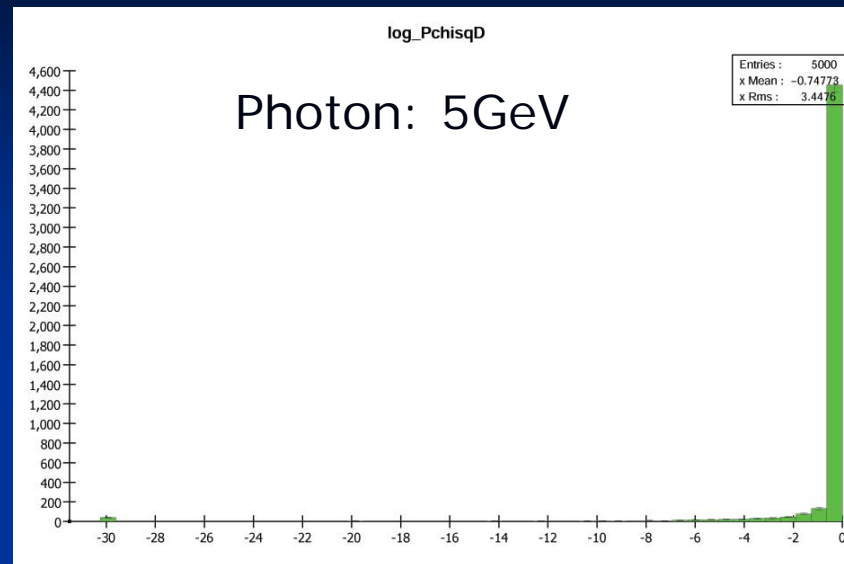

# Cluster purity : Z pole (uds) events

- Most of the clusters (89.7%) are pure (only one particle contributes)
- For the remaining 10.3% clusters
  - 55% are almost pure (more than 90% hits are from one particle)
  - The remaining clusters contain merged showers, some of them are 'trouble makers'
- On average, 1.2 merged shower clusters/Z pole event

# Photon id – longitudinal H-matrix

Still need more tuning to optimize the performance

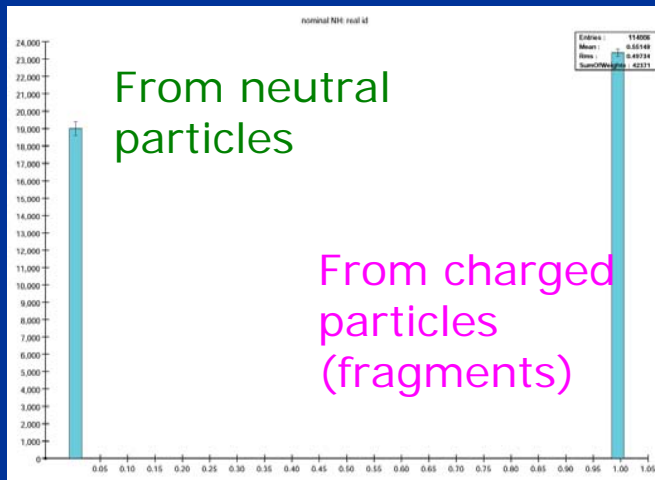

# Charge fragment identification/reduction

Energy of matched clusters

- Use geometrical parameters to distinguish real neutral hadron clusters and charge hadron fragments

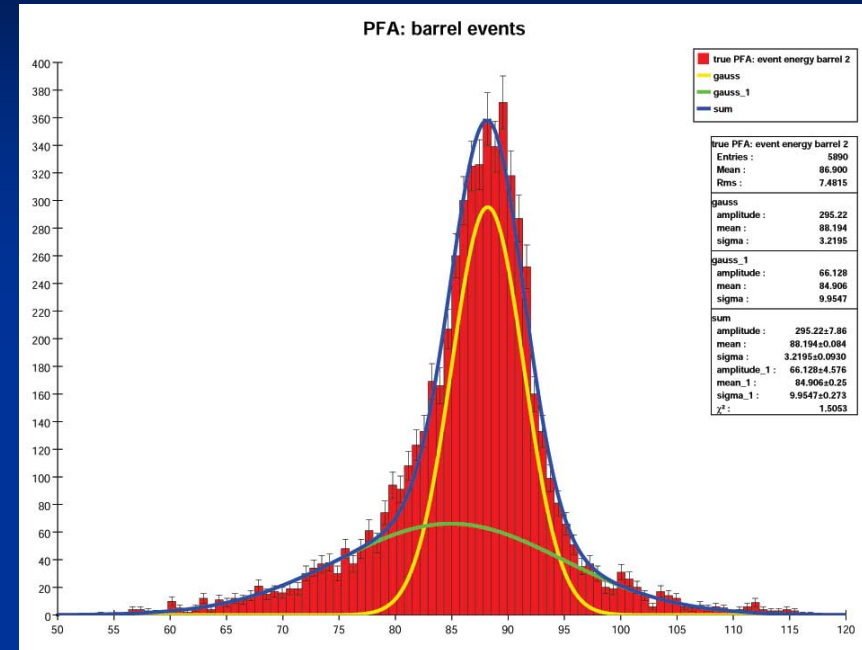

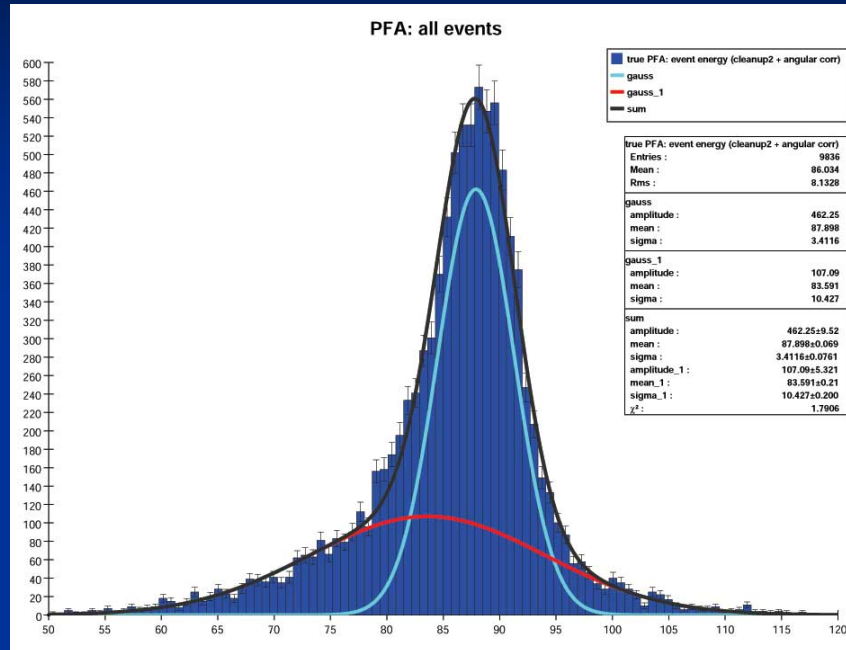

Energy of clusters not matched to any track: neutral candidate

After charge fragment identification/reduction

# PFA: Z-pole (uds) performance

All events:

3.41 GeV @87.9GeV 58.5%  
10.4 GeV 41.5%

Barrel events: 60%

3.22 GeV @88.2GeV 59%  
9.95 GeV 41%

Barrel:  $-45 \text{ deg} < \text{Theta (uds quark)} < 45 \text{ deg}$

# My un-official PFA roadmap

Infrastructure

PFA development

Test Beam

# Summery

- Particle Flow Algorithms are being developed at Argonne
  - Two 'complete' PFAs are available to play with
- Current PFA performance at Z-pole looks promising
  - Performance at Z-pole will continue to improve
  - Not a problem to achieve ILC goal at this energy range
- Need to study PFA performance over the entire ILC interested jet energy range
  - Prove that PFA is the way to achieve the ILC jet energy resolution goal
  - Use PFA to optimize ILC detector design
- Test beam data need to come in time!
