

Problems Lecture 1: Linac Basics

- 1) Calculate the relative longitudinal motion of two electrons with an energy of about 9 GeV and a difference of 3% over a distance of 21 km.
- 2) A superconducting linac consists of cavities with a length of $L = 1.1m$ and an external coupling of $Q_{ext} = 10^5$. It is operated in matched conditions (no reflected power) with a gradient $G_0 = 20MV/m$ and a beam current of $I_0 = 10mA$. and an external coupling of $Q_{ext} = 10^5$.
 - a) What is the input power P required?
 - b) The management wants to double the beam current but keep the gradient the same. In order to stay matched, which input power does one need? Which other parameter needs to be changed and how?
- 3) A harmonic oscillator is a special case of Hill's equation: $K(s) = K_0 > 0$. Show that in this case $\beta(s) = \beta_0$ fulfills Hill's equation (using the differential equation for the evolution of the beta-function). Which value has β_0 ?
- 4) How much energy is roughly stored in one ILC cavity at nominal gradient?

Solutions: Linac Basics

1) We calculate

$$\gamma = \frac{E_0}{mc^2} \approx \frac{9 \text{ GeV}}{0.511 \text{ MeV}} \approx 18000$$

then we use

$$\gamma = \frac{1}{\sqrt{1 - \beta^2}}$$

to find an approximation for β

$$\beta \approx 1 - \frac{1}{2\gamma^2} \approx 1 - 1.5 \times 10^{-9}$$

over the length of a linac 21 km the longitudinal delay compared to light is $\approx 32 \mu\text{m}$ for two particles which have a energy difference of $\Delta\gamma$ the relative longitudinal motion would be

$$\beta_1 - \beta_2 \approx \frac{1}{2\gamma^2} - \frac{1}{2(\gamma + \Delta\gamma)^2} \approx \frac{\Delta\gamma}{\gamma^3}$$

for an example of 3% the motion is $\approx 2 \mu\text{m} \ll \sigma_z$

Note: Due to the acceleration in a linac the effect would be even smaller

Solutions: Linac Basics

2)

a) In matched conditions, the input power P_0 must be equal to the power P_{beam} extracted by the beam.

We calculate

$$P_0 = P_{beam} = LG_0 I_0 = 1.1 \text{ m} \cdot 20 \text{ MV/m} \cdot 10 \text{ mA} = 220 \text{ kW}$$

b) We can calculate the required input power for matched conditions as above

$$P_{new} = P_{beam,new} = LG_0(2I_0) = 1.1 \text{ m} \cdot 20 \text{ MV/m} \cdot 20 \text{ mA} = 440 \text{ kW} = 2P_0$$

So the input power has to double.

However we would not be matched any more if we did not change the coupling of the cavity to the RF. So we need to couple the cavity more strongly to the RF power source. The energy in the cavity E remains the same since the gradient is not changed. But the input power doubles. We use

$$Q_{ext,new} = \frac{E}{P_{new}}\omega = \frac{E}{2P_0}\omega = \frac{1}{2} \frac{E}{P_0}\omega = \frac{1}{2} Q_{ext,old} = 0.5 \cdot 10^5$$

Solutions: Linac Basics

3) We use $K(s) = \text{const} > 0$.

- We know the solution for a harmonic oscillation with a fixed amplitude

$$x = A \cos(\phi(s) + \phi_0)$$

for the beta-function this should correspond to a constant value of beta, which we call β_0

- We now need to check that this fulfills the differential equation for β
 - Ansatz: $\beta = \beta_0$, $\beta' = 0$ and $\beta'' = 0$:

$$\begin{aligned} \frac{\beta'' \beta}{2} - \frac{\beta'^2}{4} + K\beta^2 &= 1 \\ \Rightarrow K\beta_0^2 &= 1 \end{aligned}$$

Hence

$$\beta_0 = \frac{1}{\sqrt{K}}$$

Now one can plug this into the equation of motion to see that one recovers the known solution for a harmonic oscillator. ϵ is defined by the initial condition. See next page

Solutions: Linac Basics

Replacing K by $1/\beta_0^2$ in the original equation

$$x''(s) + \frac{1}{\beta_0^2}x = 0$$

we know the solution for a harmonic oscillator

$$x = A \cos\left(\frac{s}{\beta_0} + \phi_0\right)$$

On the other hand, assuming $\beta(s) = \beta_0$ in the Hill's equation we obtain

$$x = \sqrt{\epsilon\beta_0} \cos(\phi(s) + \phi_0) = \sqrt{\epsilon\beta_0} \cos\left(\frac{s}{\beta_0} + \phi_0\right)$$

So the harmonic oscillator is as expected a special case for the Hill's equation.

This is obviously no surprise, but the goal has been to make you use the equation a bit.

Solutions: Linac Basics

4) Assuming $R/Q = 1 \text{ k}\Omega$ and a length of about $L = 1 \text{ m}$, we find approximately 120 J

$$E = \frac{G^2 L^2}{2\pi f_{RF} R/Q}$$
