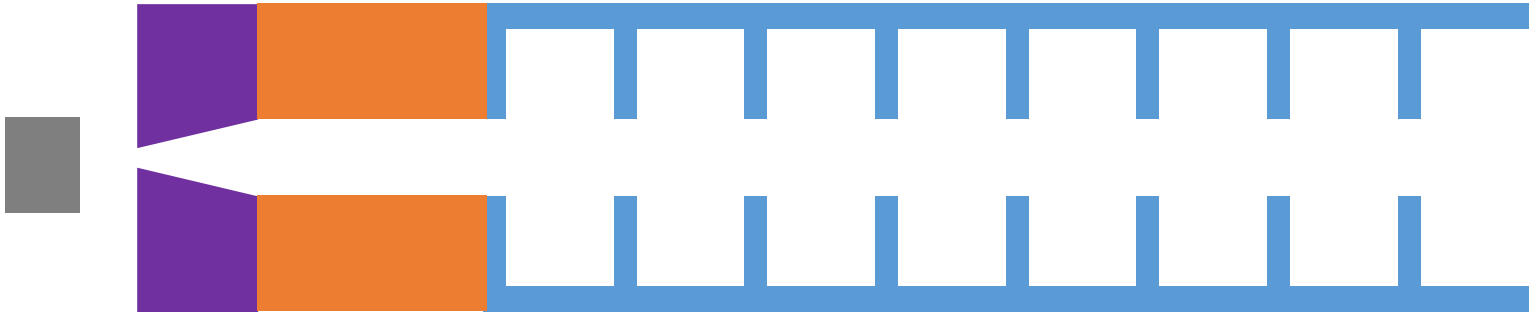
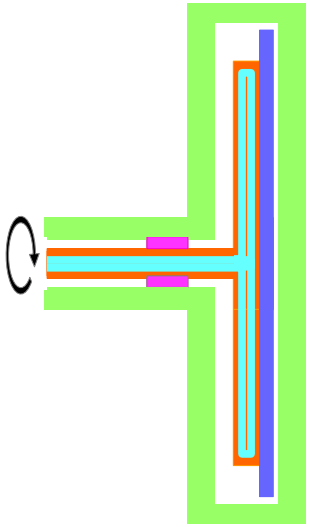
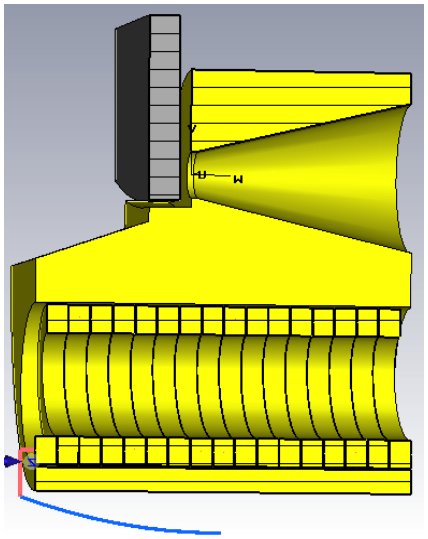
Geometry

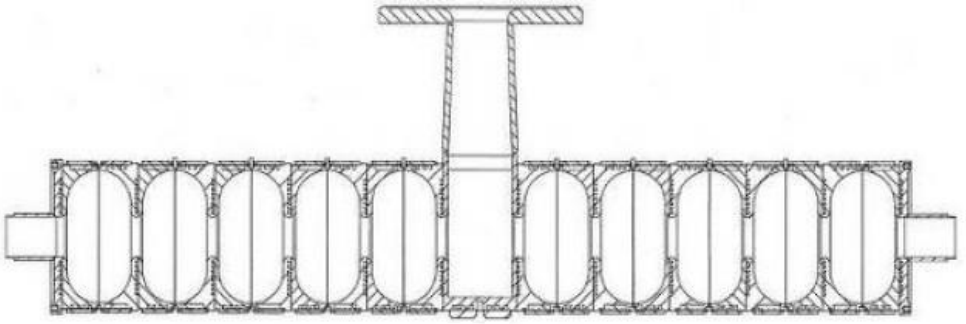




Rotating Target



Flux Concentrator

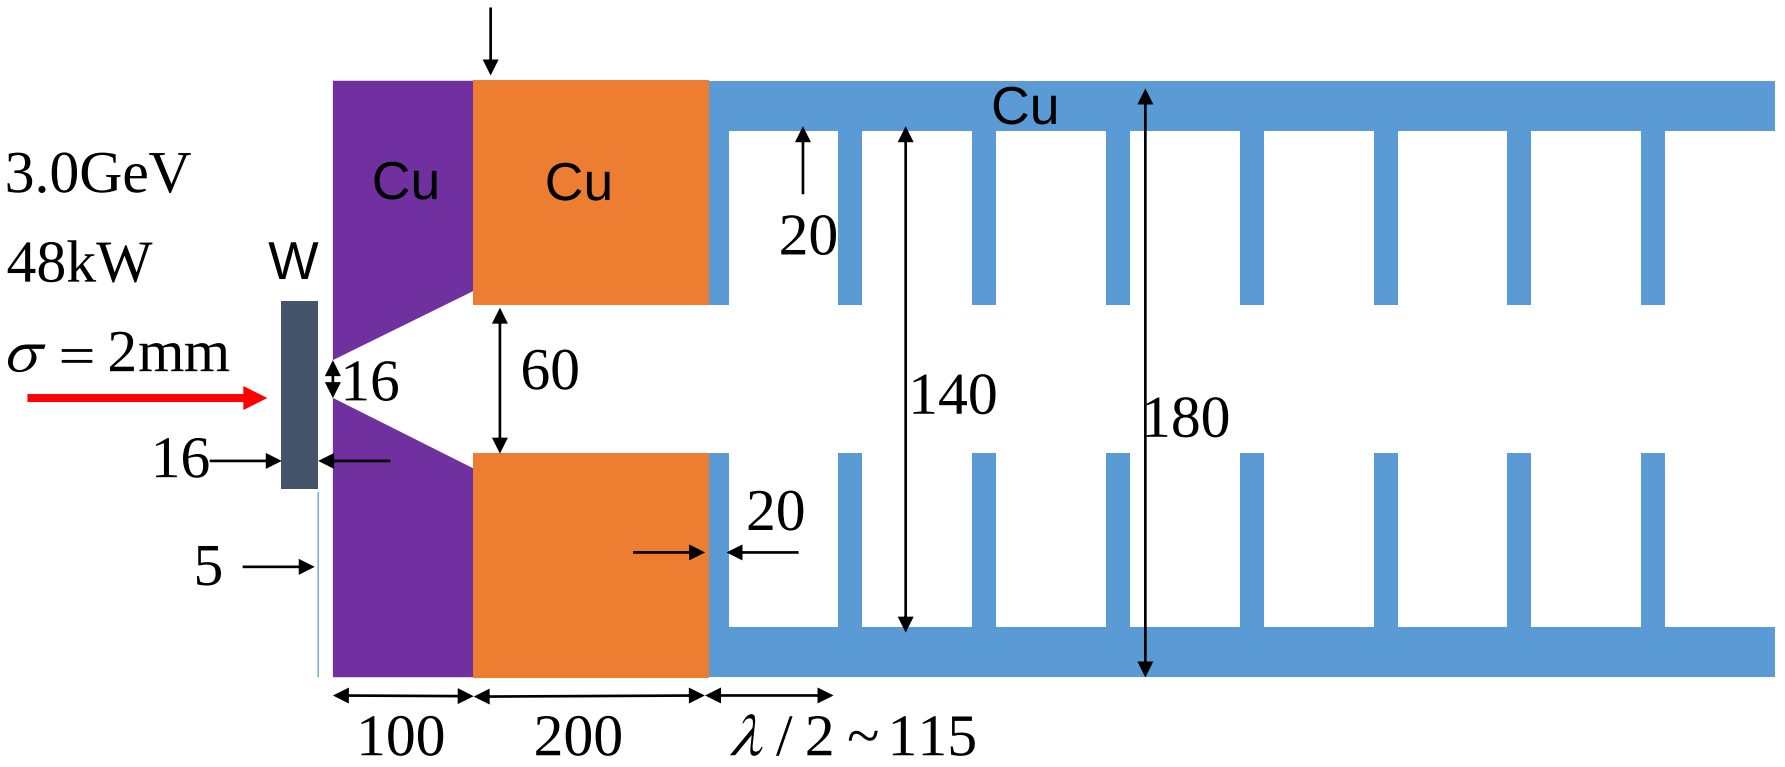


capture linac

Parameters and geometry in Geant4

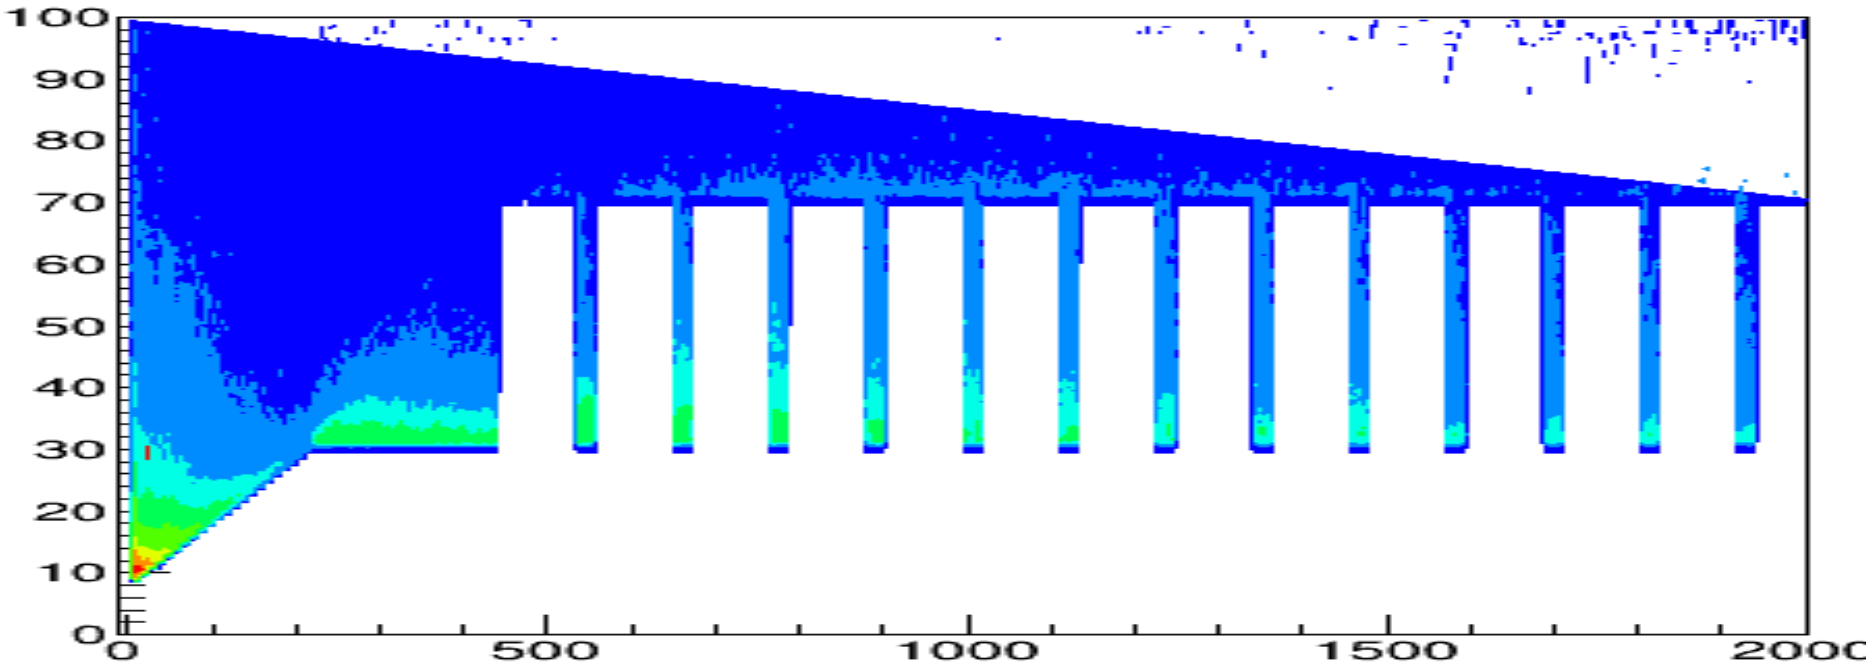
1320 bunches

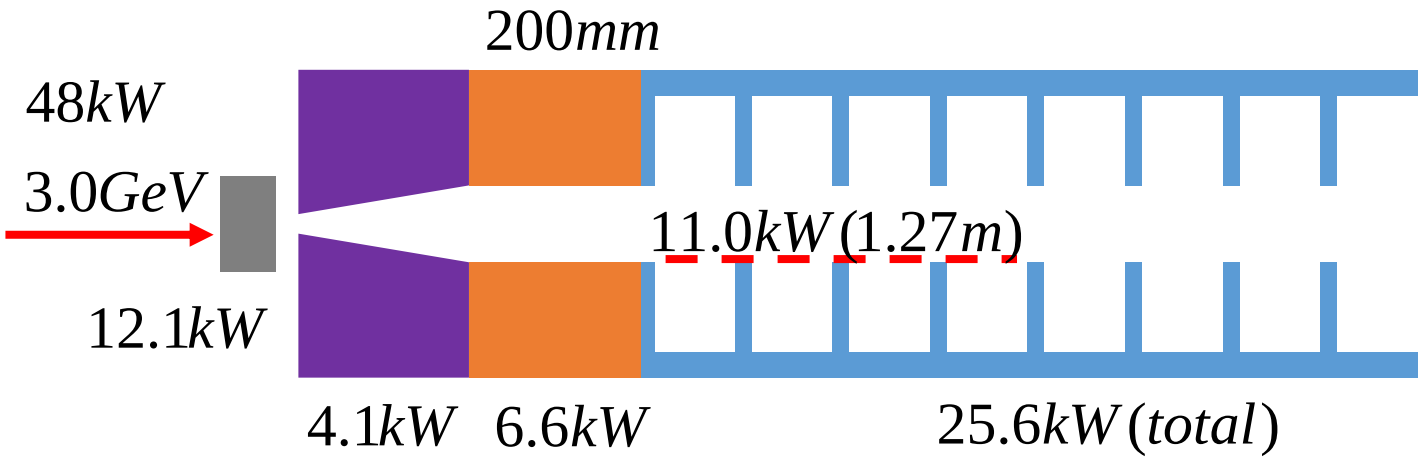
Ee	σe-	e-/bunch	Beam Power	Total thickness
GeV	mm	nC	kW	mm
3.0	2	2.4	48	16



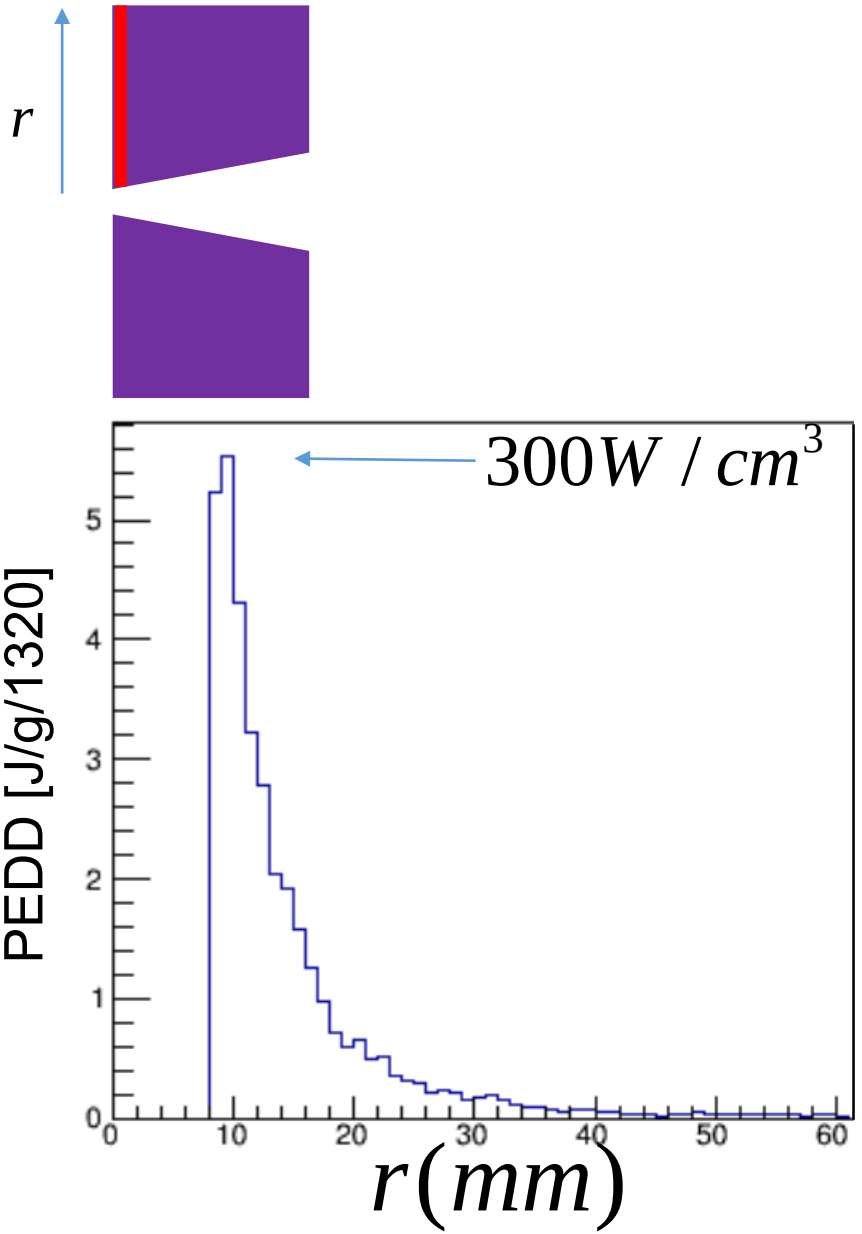
All parameters are consistent with Kuriki's tracking simulation

Summary of the calculation





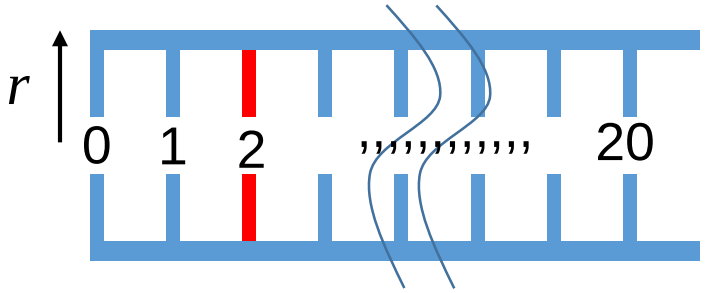
PEDD(1320 bunches) in FC

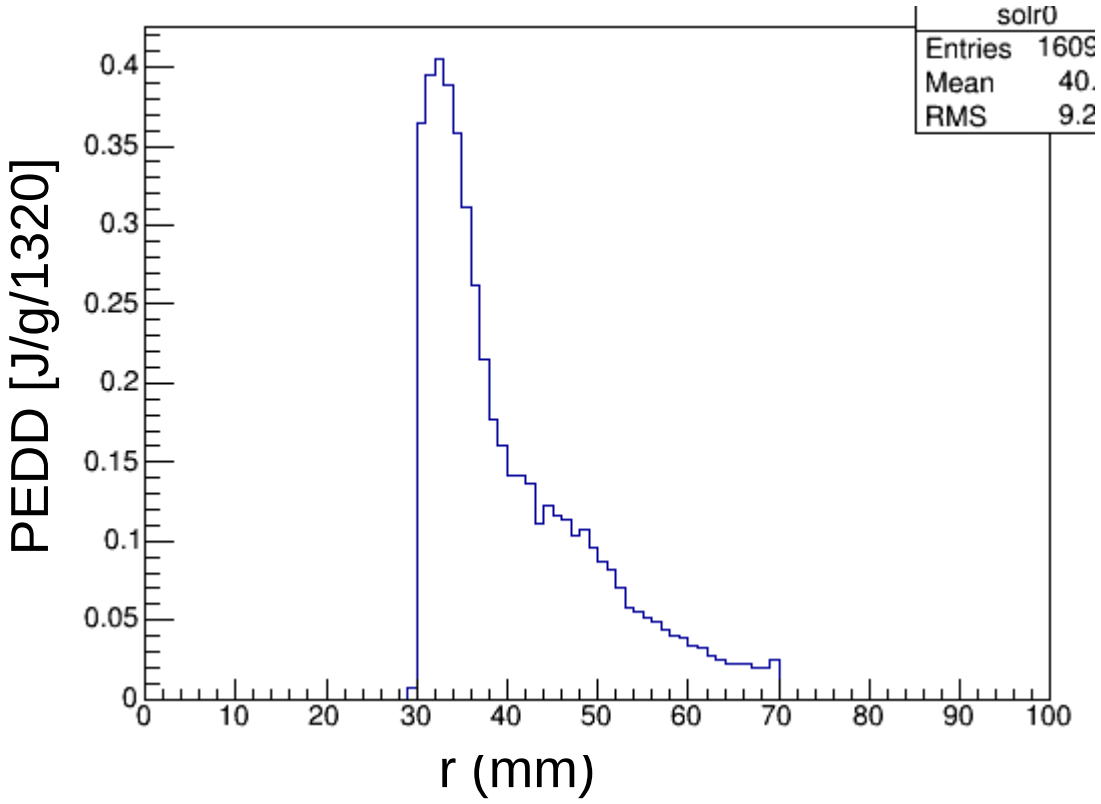


Less than the limit for Cu (7~12 J/g)* with 1320 bunches (~ 64ms).

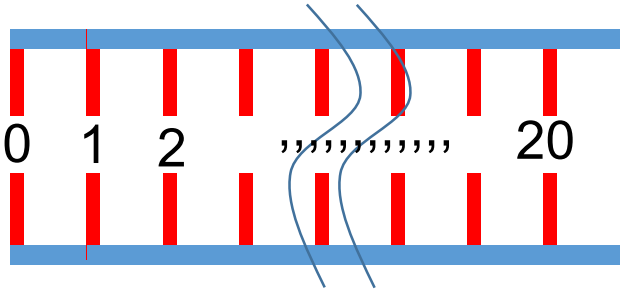
*TESLA-FEL-2006-05

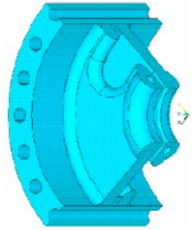
PEDD in irises the capture linac

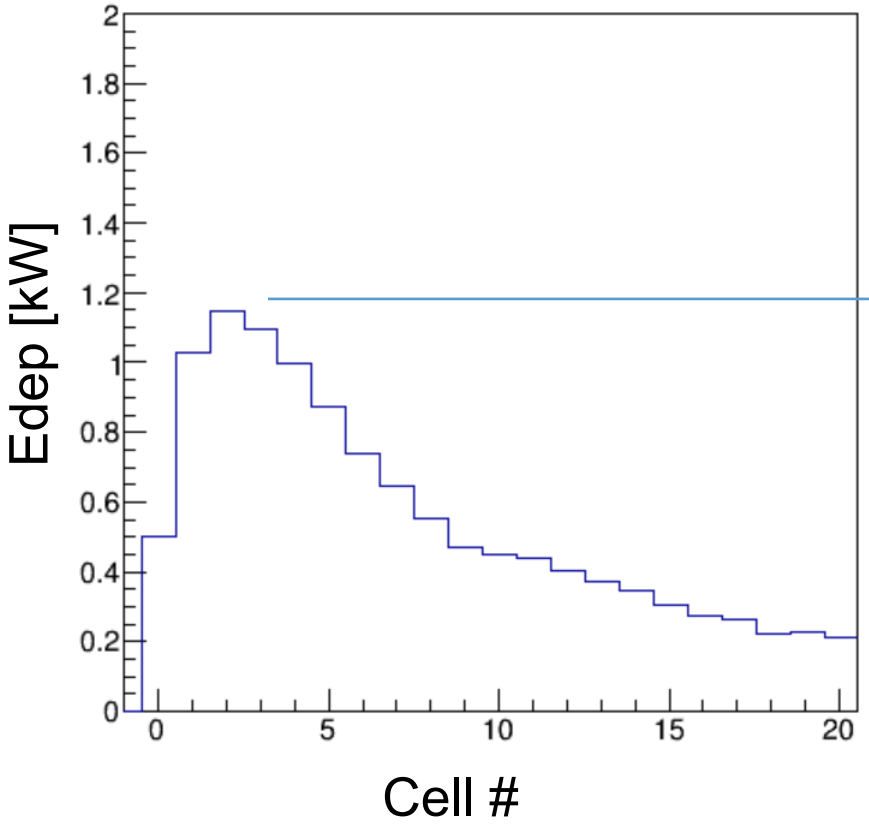




Energy deposit in irises the capture linac



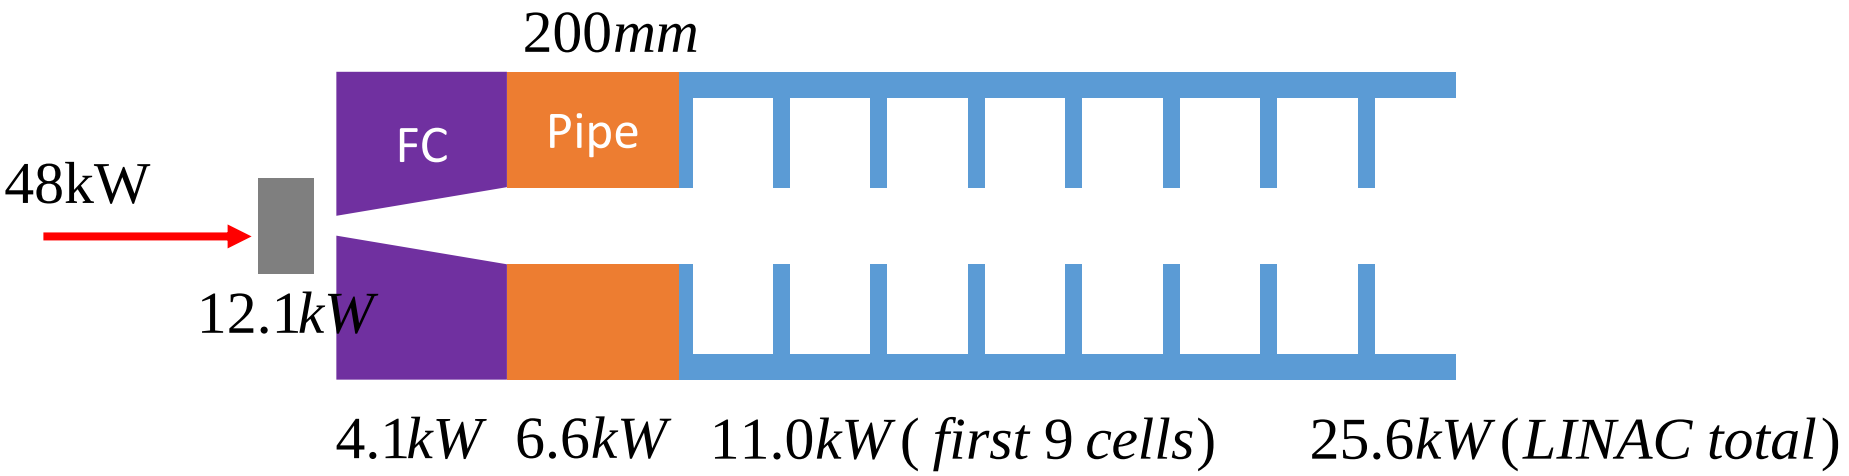




Detuning -38.2kHz/7.4kW in an iris
(an estimate from SLAC-PUB-11767)

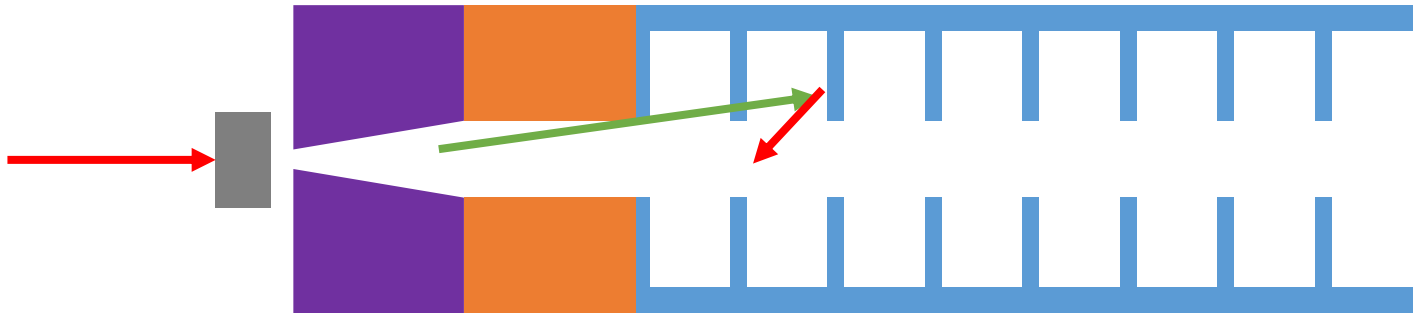
38.2 x 1.2/7.4 =6.2 kHz
at the worst point
is less than the bandwidth of 44 kHz

Summary of the energy deposition



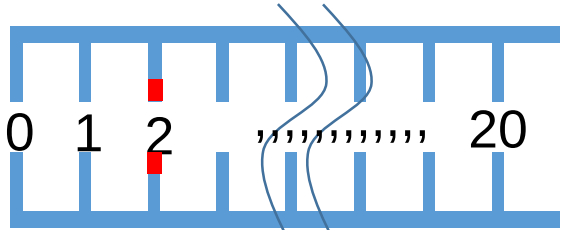
Target	$16.3kW$
Pipe	$6.6kW$
Flux Concentrator	$4.1kW(beam)+14kW(ohmic)$ PEDD=6J/g(1320bunch)=0.3kW/cm^3
Capture Linar	$25.6kW(total)$ $3.32kW(RF)\ per\ 9Cell(tube)$ $11.0kW(beam)+3.32kW(RF)\ in\ first\ 9Cell$

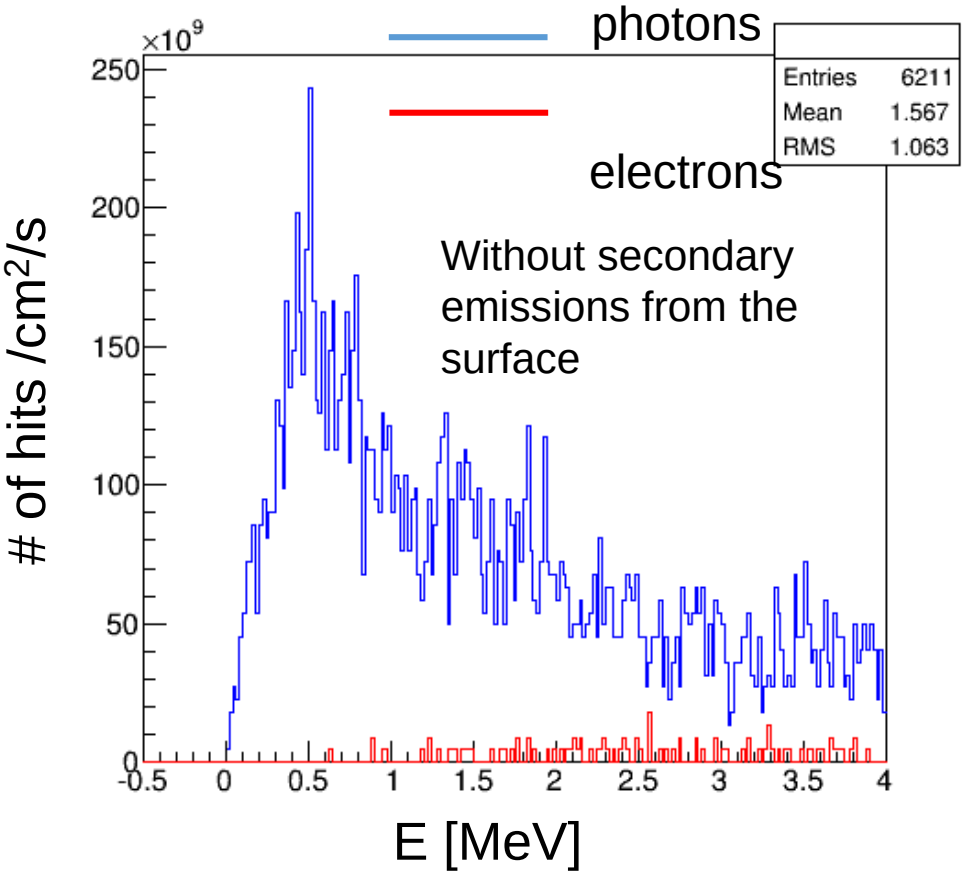
Further issues

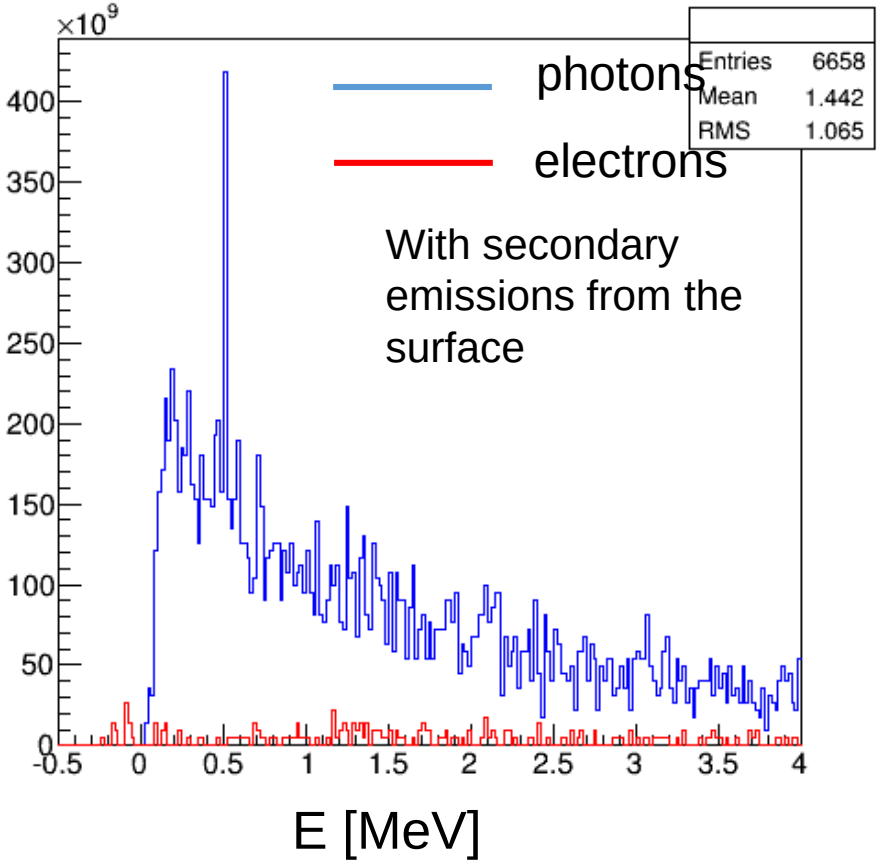


- Secondary emissions from the RF structure
  - Could be a source of discharge?
- Radiation dose
  - for shielding/handling desigen

Particles hitting the RF surface

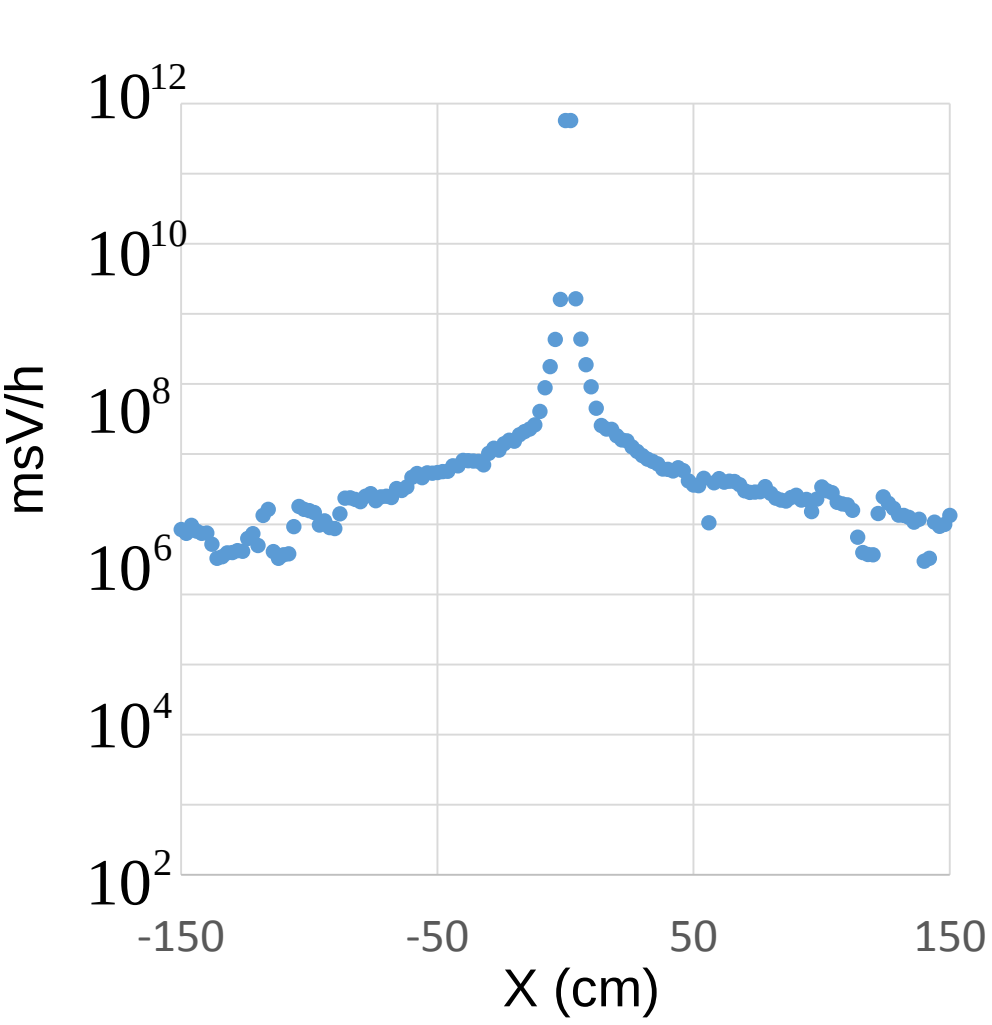




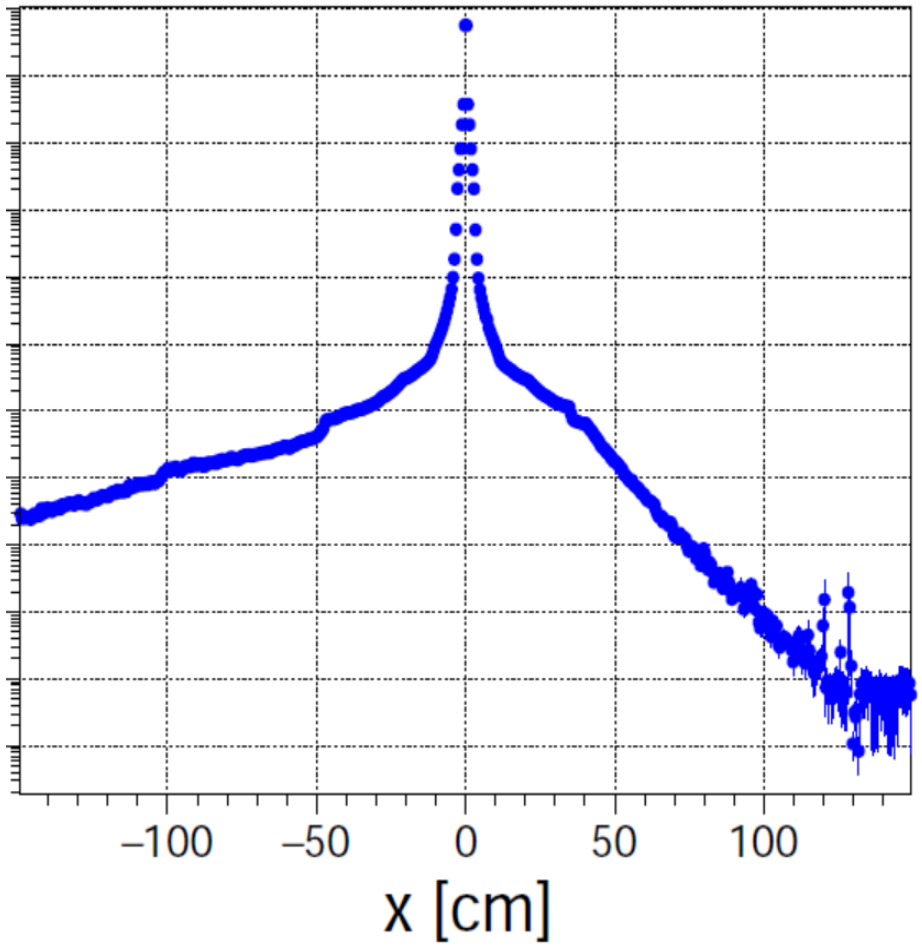


Simulation of low enegy particles is tricky

Effetive Dose(2600 bunch at LCWS2015)

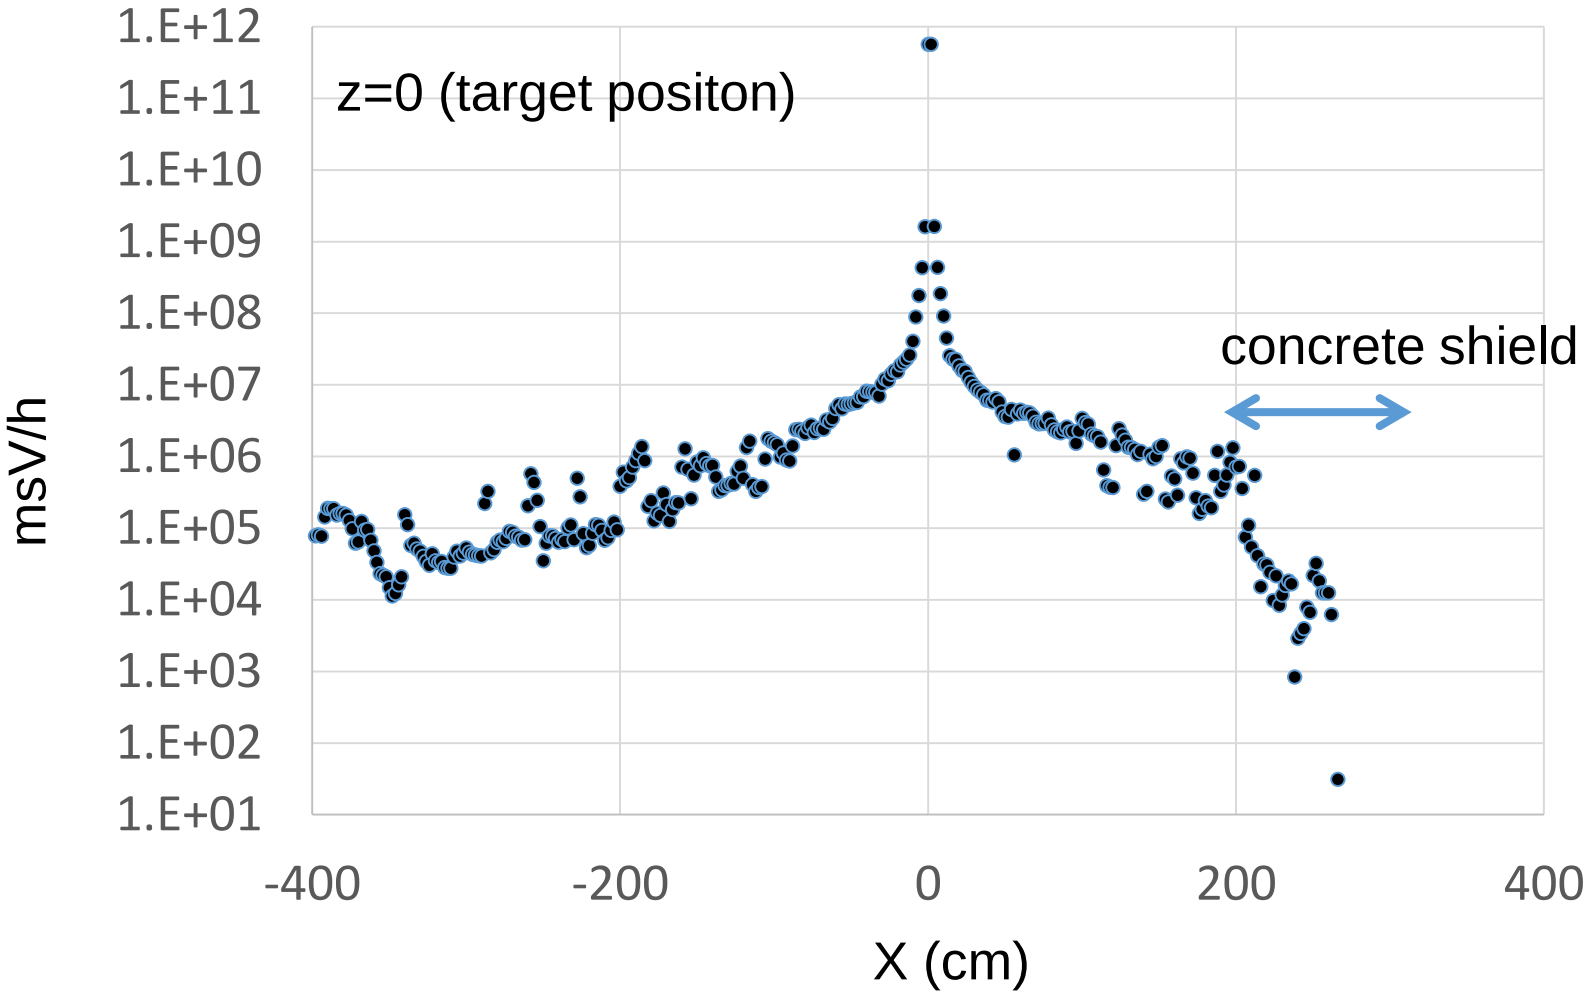


Ushakov LCWS2015



Electron driven and undualtor: radiation levels are more or less the same
Deference at x > 50 cm due to difference of materials around the target

Effetive Dose (2600 bunches at LCWS2015)



Prospects

- Energy deposition themselves does not seem to be serious issues for e-driven target now, while engineering design of the cooling system is necessary.

- Further considerations are needed
  - Secondary particles
    - SuperKEKB may a good experience
  - Radiation dose estimate
