

Measuring the CP state of tau lepton pairs from Higgs decay at the ILC

arXiv:1804.01241 submitted to PRD

<u>Daniel Jeans</u>, Graham Wilson ALCW18, Fukuoka

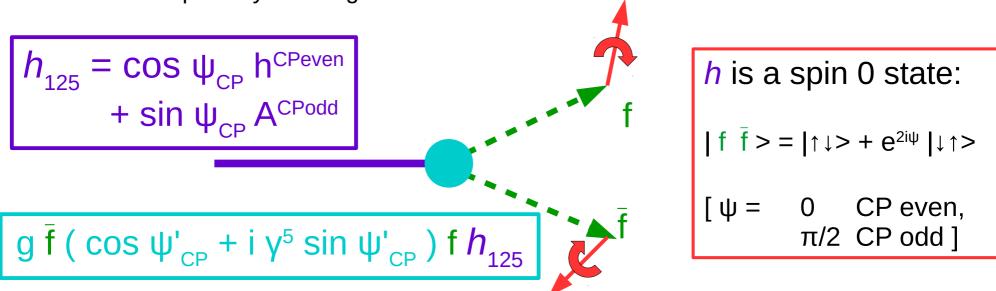

Motivation

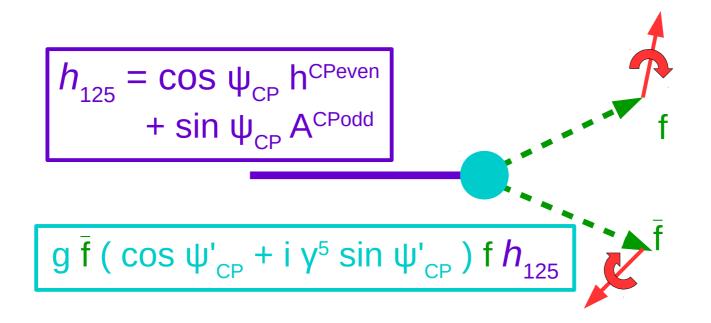

Is the 125 GeV Higgs a CP eigenstate ? $h_{125} = \cos \psi_{CP} h^{CPeven} + \sin \psi_{CP} A^{CPodd}$ pure CP even: $\psi_{CP} = 0$ [Standard Model] odd: $\psi_{CP} = \pi/2$ [excluded at LHC] or a mixture?

Do Higgs couplings conserve CP ? e.g. coupling to fermions: L ~ g \bar{f} (cos ψ_{CP} + i γ^{5} sin ψ_{CP}) f H

CP conserving coupling maximally violating or partially violating ? $\Psi_{CP} = 0$ [Standard Model] $\Psi_{CP} = \pi/2$

The correlation between spins of Higgs decay products is sensitive to their CP state [in particular, the transverse correlation]

why use tau leptons to measure CP in Higgs sector?

- fermion: tree-level CP effects possible

(H \rightarrow WW, ZZ only via loops)

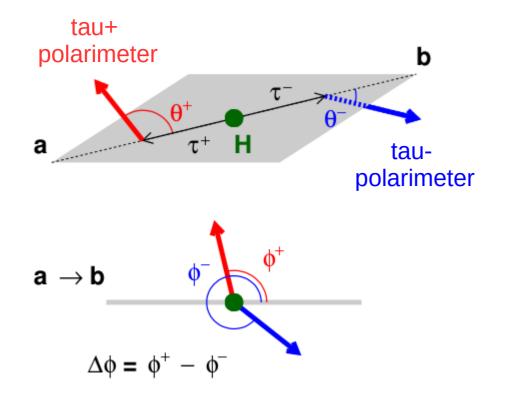

- unstable fermion:
 - distribution of tau decay products gives
 - access to tau spin direction

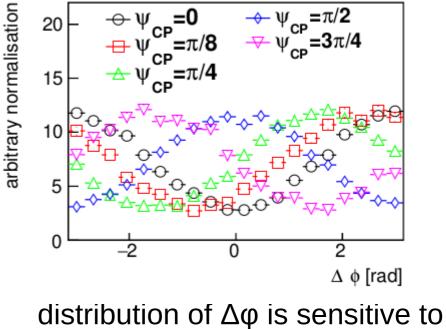

optimal estimator = "polarimeter vector"

easy to extract for tau+ \rightarrow (pi+ nu) and tau+ \rightarrow (pi+ pi0 nu) decay modes

- reasonable 6% branching ratio

- clean separation of the two fermion decays (no colour string as in $H \rightarrow bb)$

CP mixing angle ψ_{CP}

amplitude of modulation in $\Delta \phi$ varies from event to event, depending on θ^{\pm} , according to contrast function:

$$c(\theta^+, \theta^-) \equiv \sin \theta^+ \sin \theta^- / (1 + \cos \theta^+ \cos \theta^-)$$

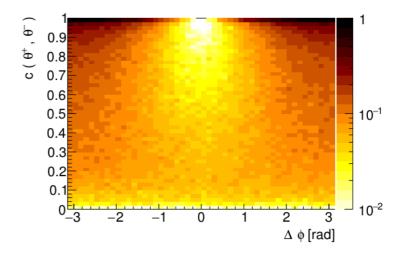

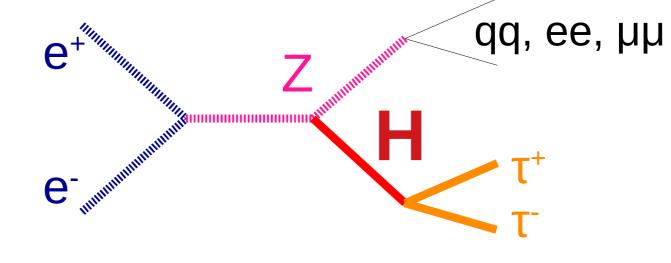

FIG. 3. Two-dimensional distribution of events in $\Delta \phi$ and $c(\theta^+, \theta^-)$ at MC truth level, for the case $\psi_{\rm CP} = 0$.

In this analysis, we measure ψ_{CP} of the tau pair from Higgs decay in a model-independent way, by measuring the phase of the $\Delta \phi$ distribution

we don't try to understand which mechanism creates the mixing: explicitly CP violating coupling, mixed CP mass eigenstate, ... → requires combination with other measurements, model assumptions, ... Analysis uses full ILD simulation signal and SM backgrounds standard data reconstruction (ilcsoft v01-16-02)

SM backgrounds: $e^+ e^- \rightarrow ff H, 4f, 2f$

assume 2 ab⁻¹ of 250 GeV data: "H20-staged"

Full tau reconstruction

to reconstruct tau polarimeter, need full reconstruction of tau decay products, including the neutrino(s)

in hadronic tau decays (# neutrino = 1), if we know the tau production vertex, the impact parameters of charged tau decay products, the p_T of the tau-tau system,

then the neutrino momenta can be reconstructed:

6 unknowns/event:

2 x neutrino 3-momenta

6 constraints/event:

2 x impact parameter defines plane of tau momentum

2 x tau invariant mass

2 from event $p_T [p_x, p_y] \rightarrow$ insensitive to ISR / beamstrahlung

[+ solve two-fold ambiguities from quadratic constraints using tau lifetime, and, only if necessary, using reconstructed tau-tau mass]

TABLE IV. Estimated experimental precision $\delta \psi_{CP}$ on the CP phase in different scenarios.

sanity check: output = input phase

sensitivity on Ψ_{CP} : 2/ab, all channels: 75 mrad

dominated by events with hadronic Z decay

perfect reconstruction, selection: 25 mrad sensitivity

summary

demonstrated, using full detector simulation and backgrounds, that CP mixing in tau-pair from Higgs decays can be determined to 75 mrad ~ 4.3 deg using 2 ab-1 of ILC250 data

potential for improved analysis methods to significantly improve results [ultimately \rightarrow 25 mrad]

using only a few tau decay modes

 \rightarrow can probably increase sensitivity by also using other modes
