

The New CALICE SiPM-on-Tile HCAL Prototype: Software and First Look into Test Beam Data

May 29th, 2018

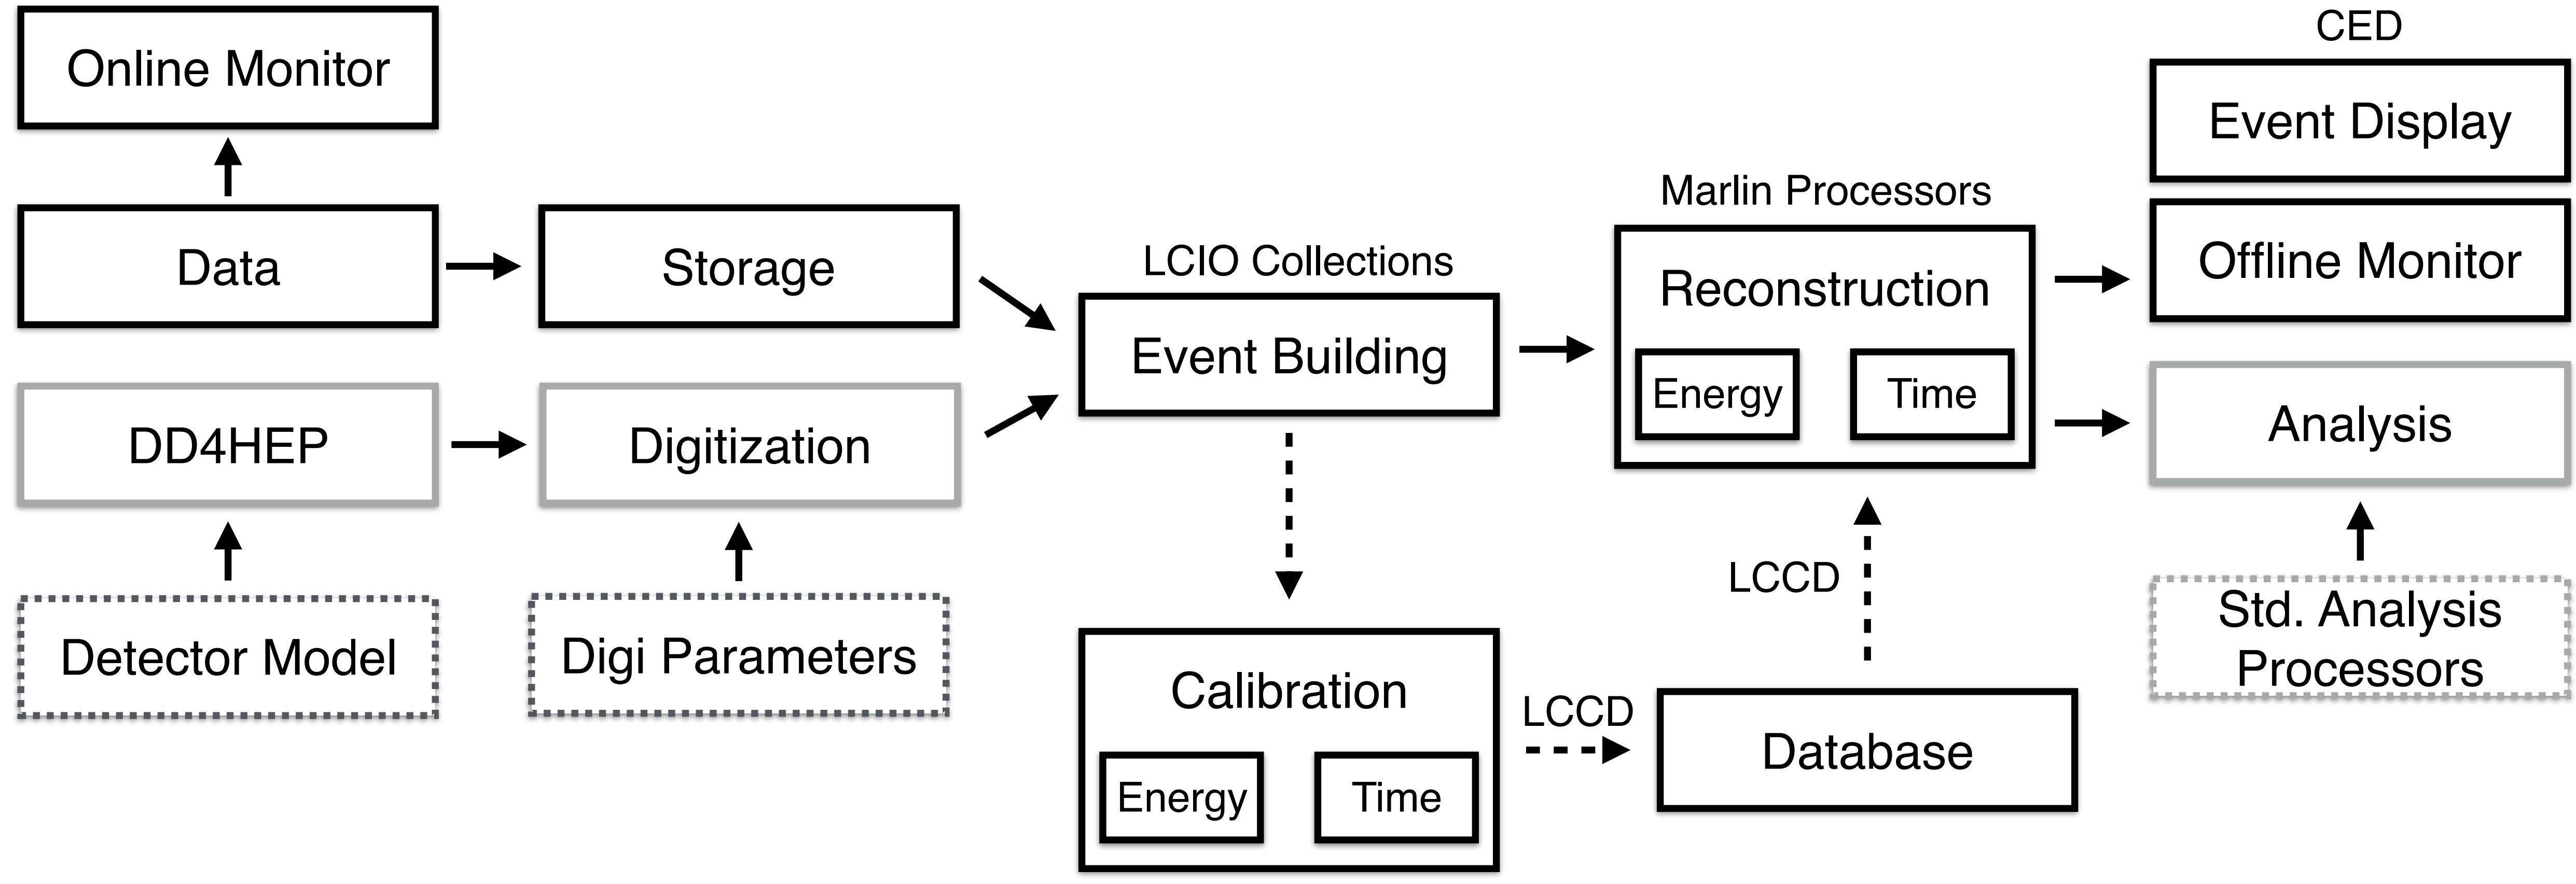

Asian Linear Collider Workshop 2018, Fukuoka

Christian Graf

On behalf of the CALICE Collaboration

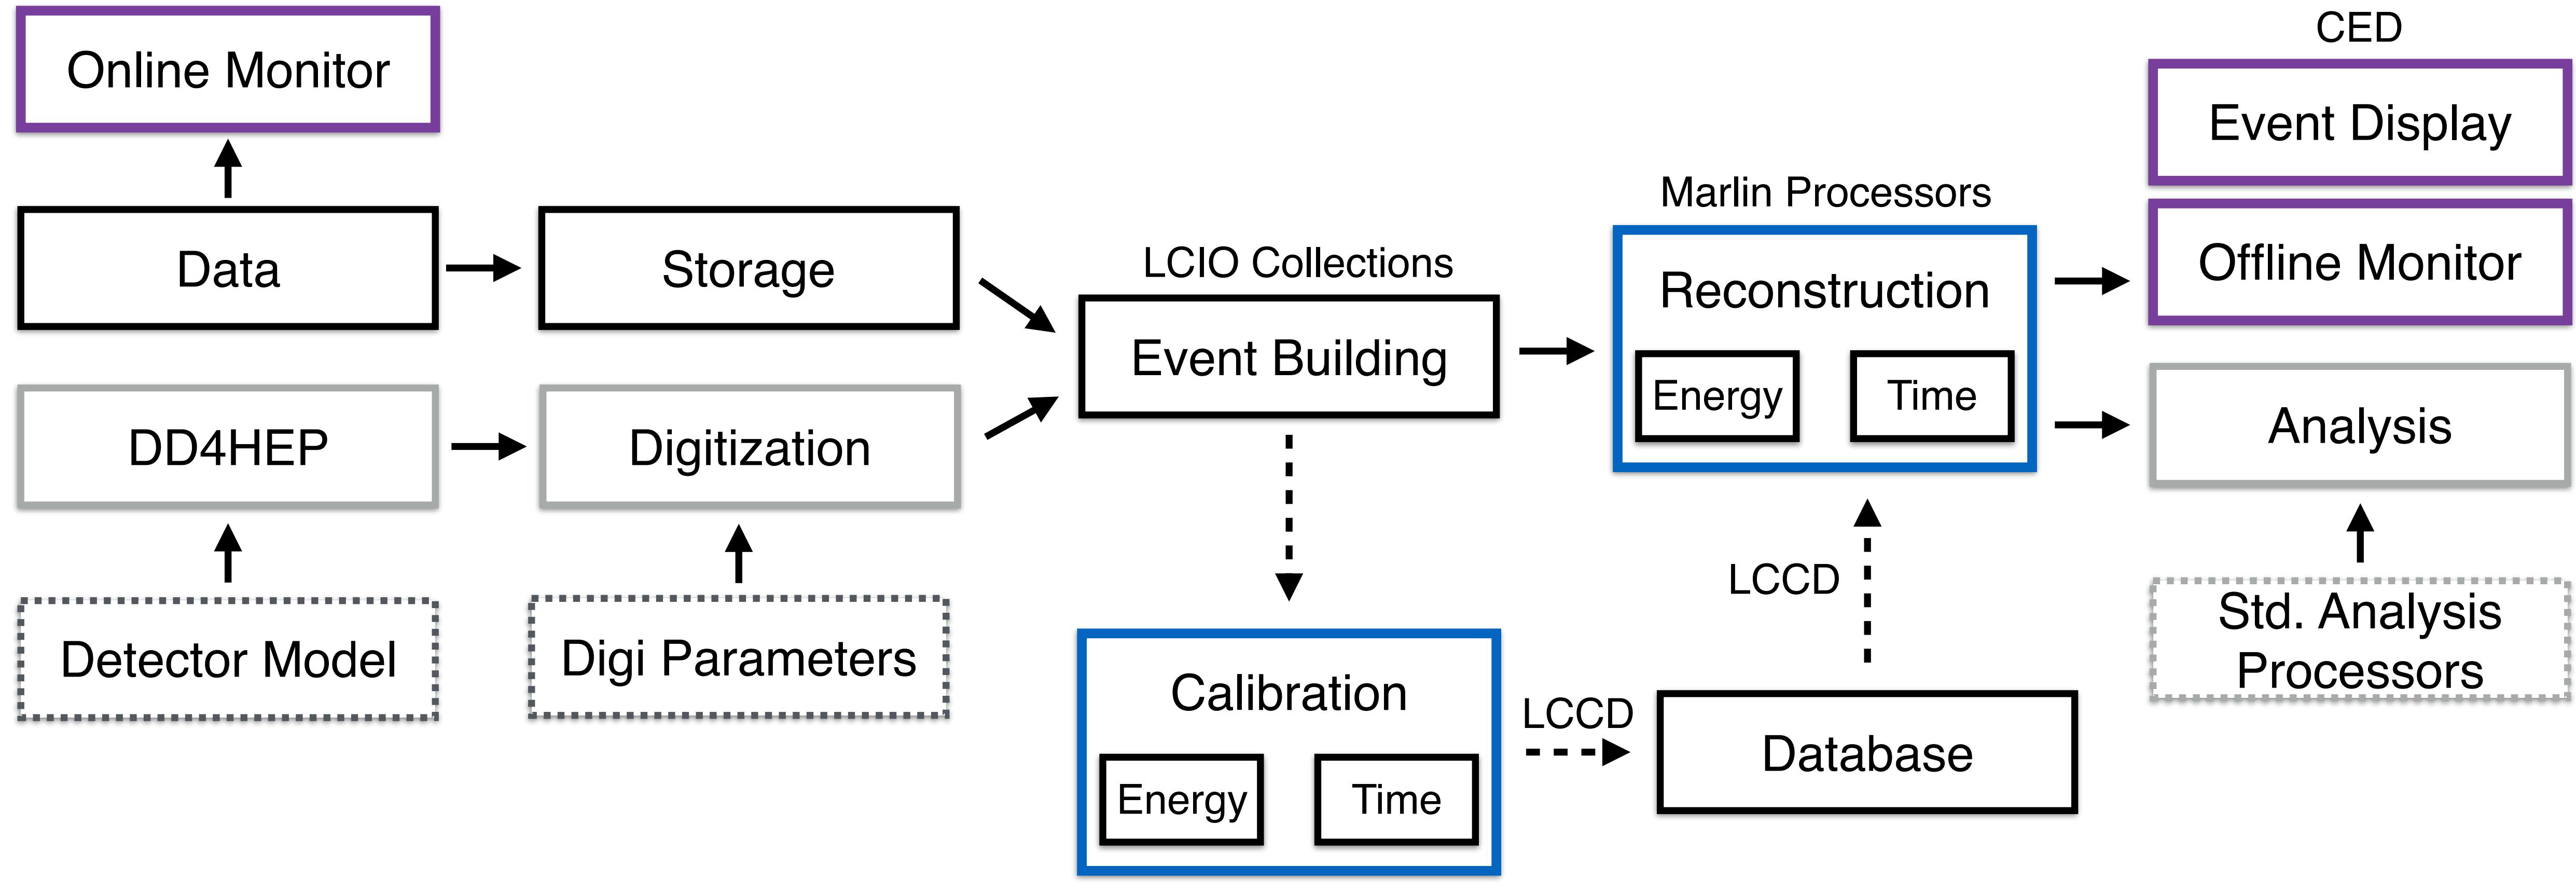

Overview - Software Workflow

- Rely on ILCSoft
- Software chain build with future linear collider experiment in mind
 - validation of simulations
- Data and simulation are processed by the same pipeline

Overview - Software Workflow

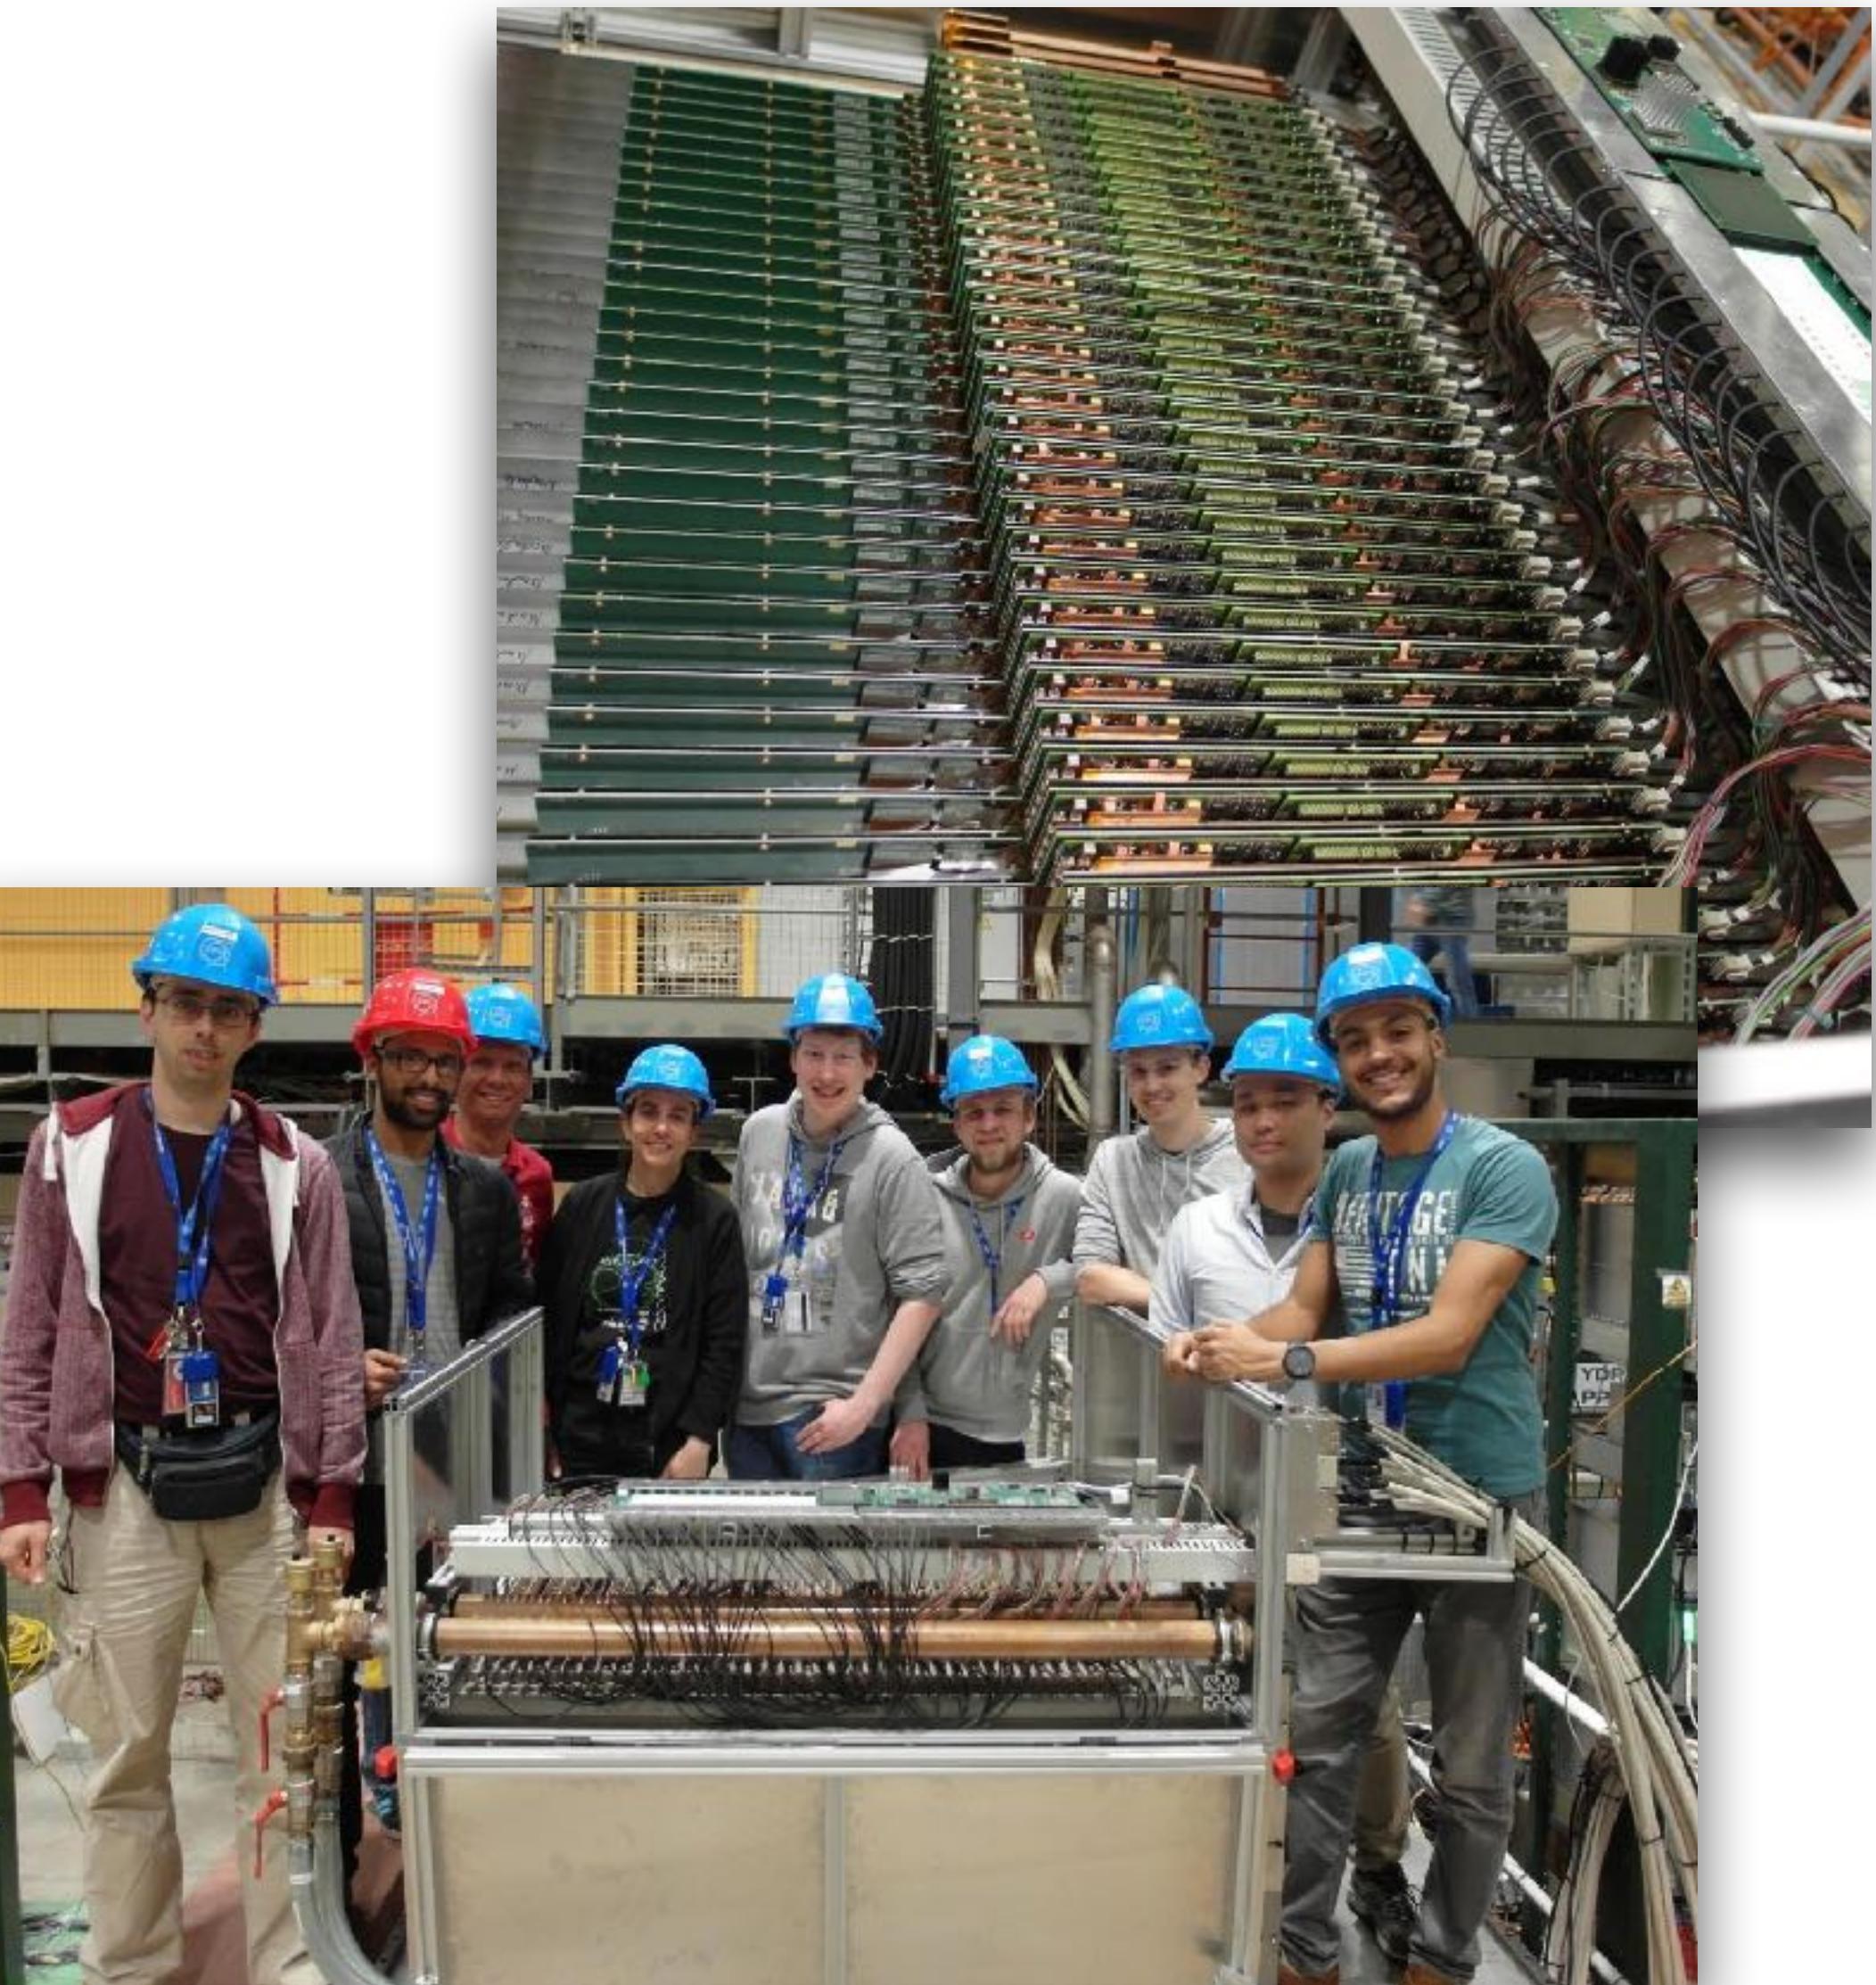

- Rely on ILCSoft
- Software chain build with future linear collider experiment in mind
 - validation of simulations
- Data and simulation are processed by the same pipeline

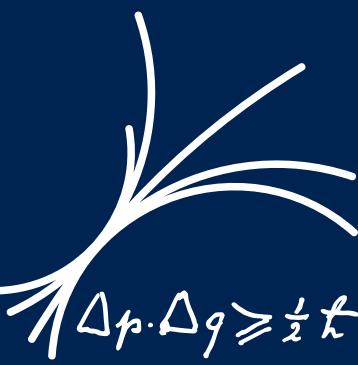

Test Beam Campaign at CERN / SPS

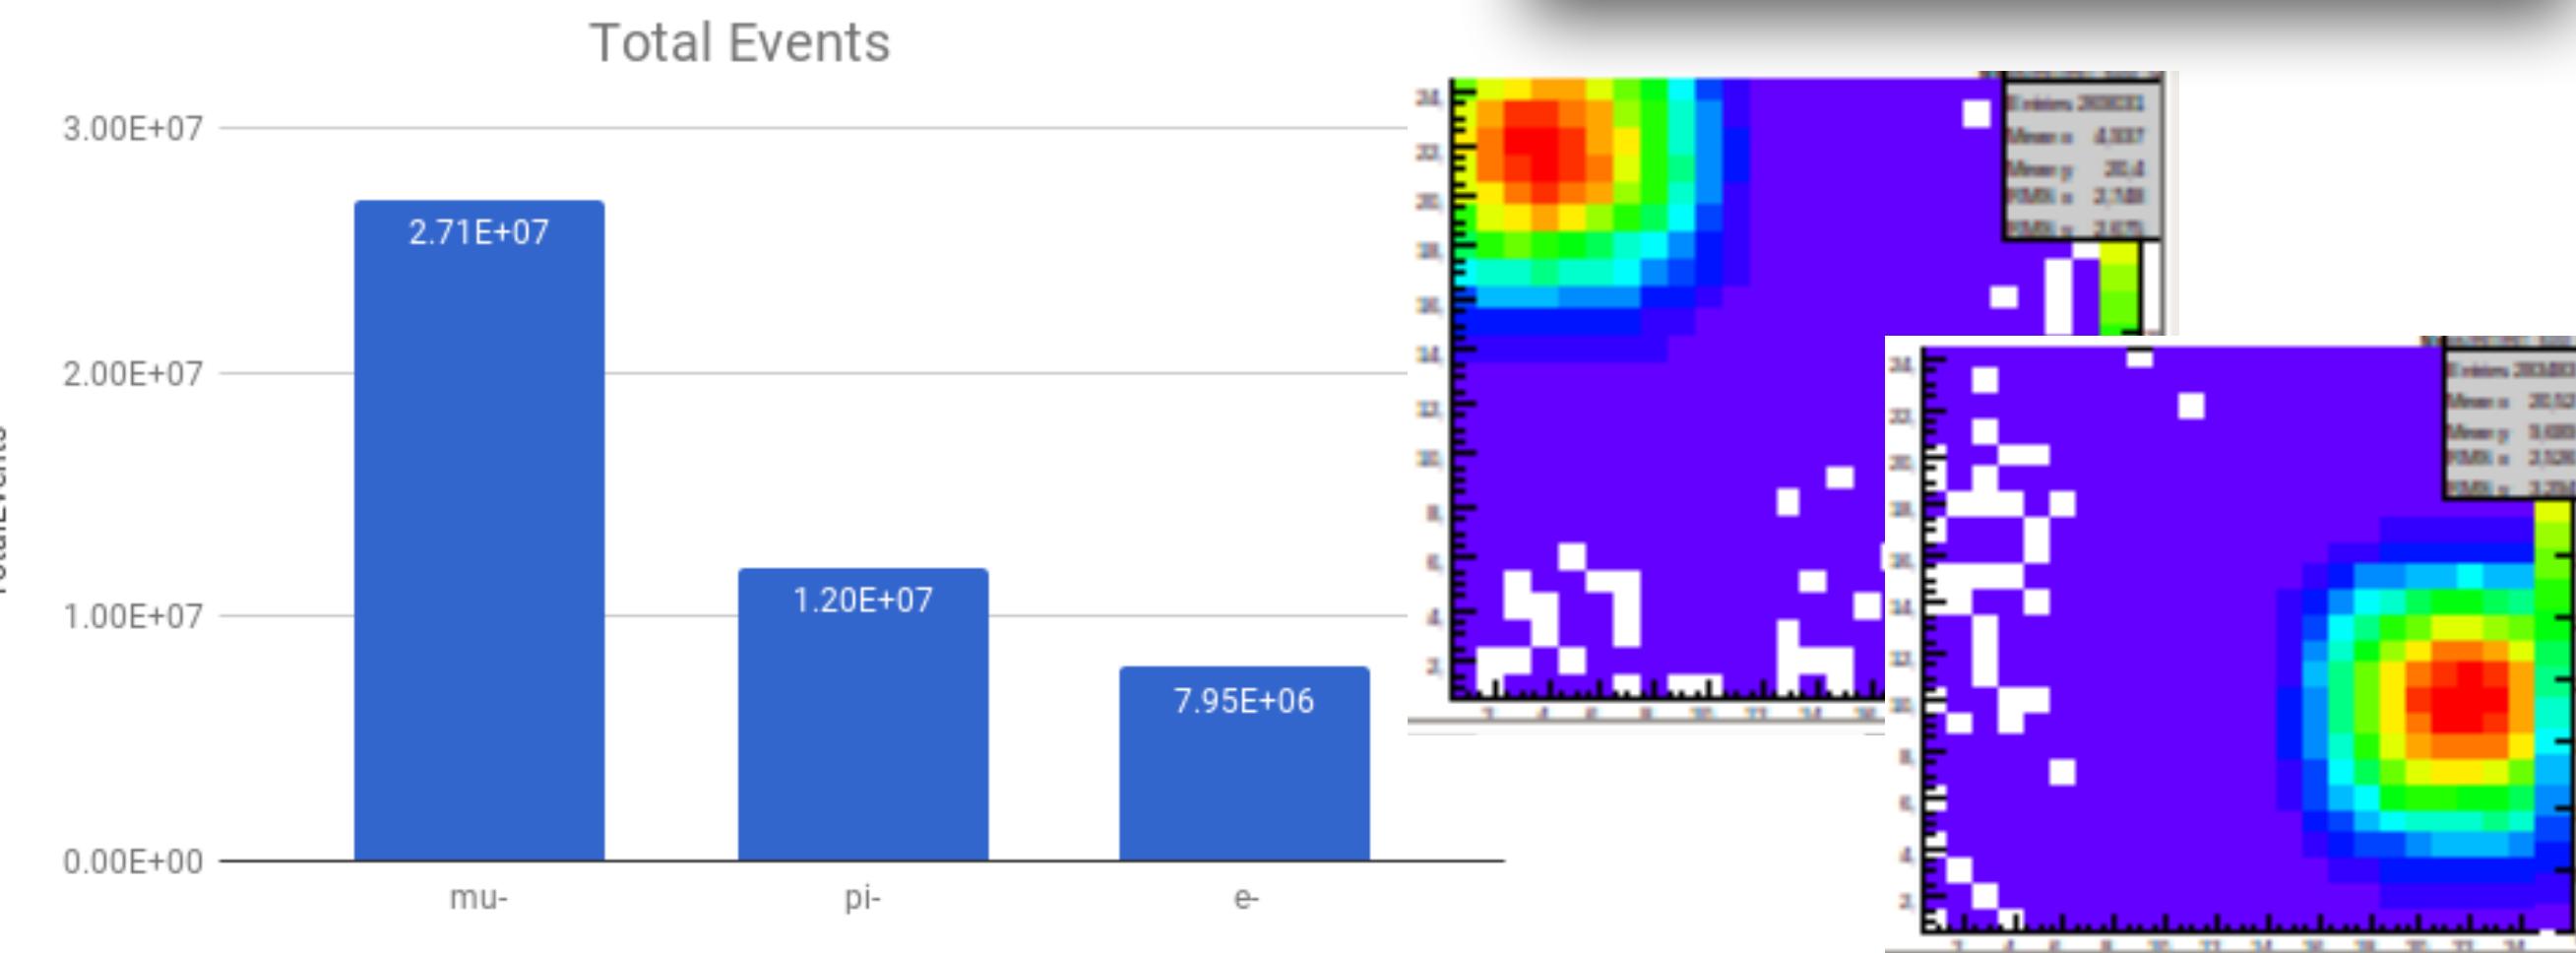

- CERN / SPS H2 beam line (9.5. - 23.5.18)
- Installation of 38 layers, nearly 22,000 channels
- **Technical Objectives:**
 - prove concept of scalable scintillator on tile design
 - reliable operation of large prototype
- **Scientific Objectives:**
 - energy linearity
 - hit time analysis
 - shower profiles

Run Program

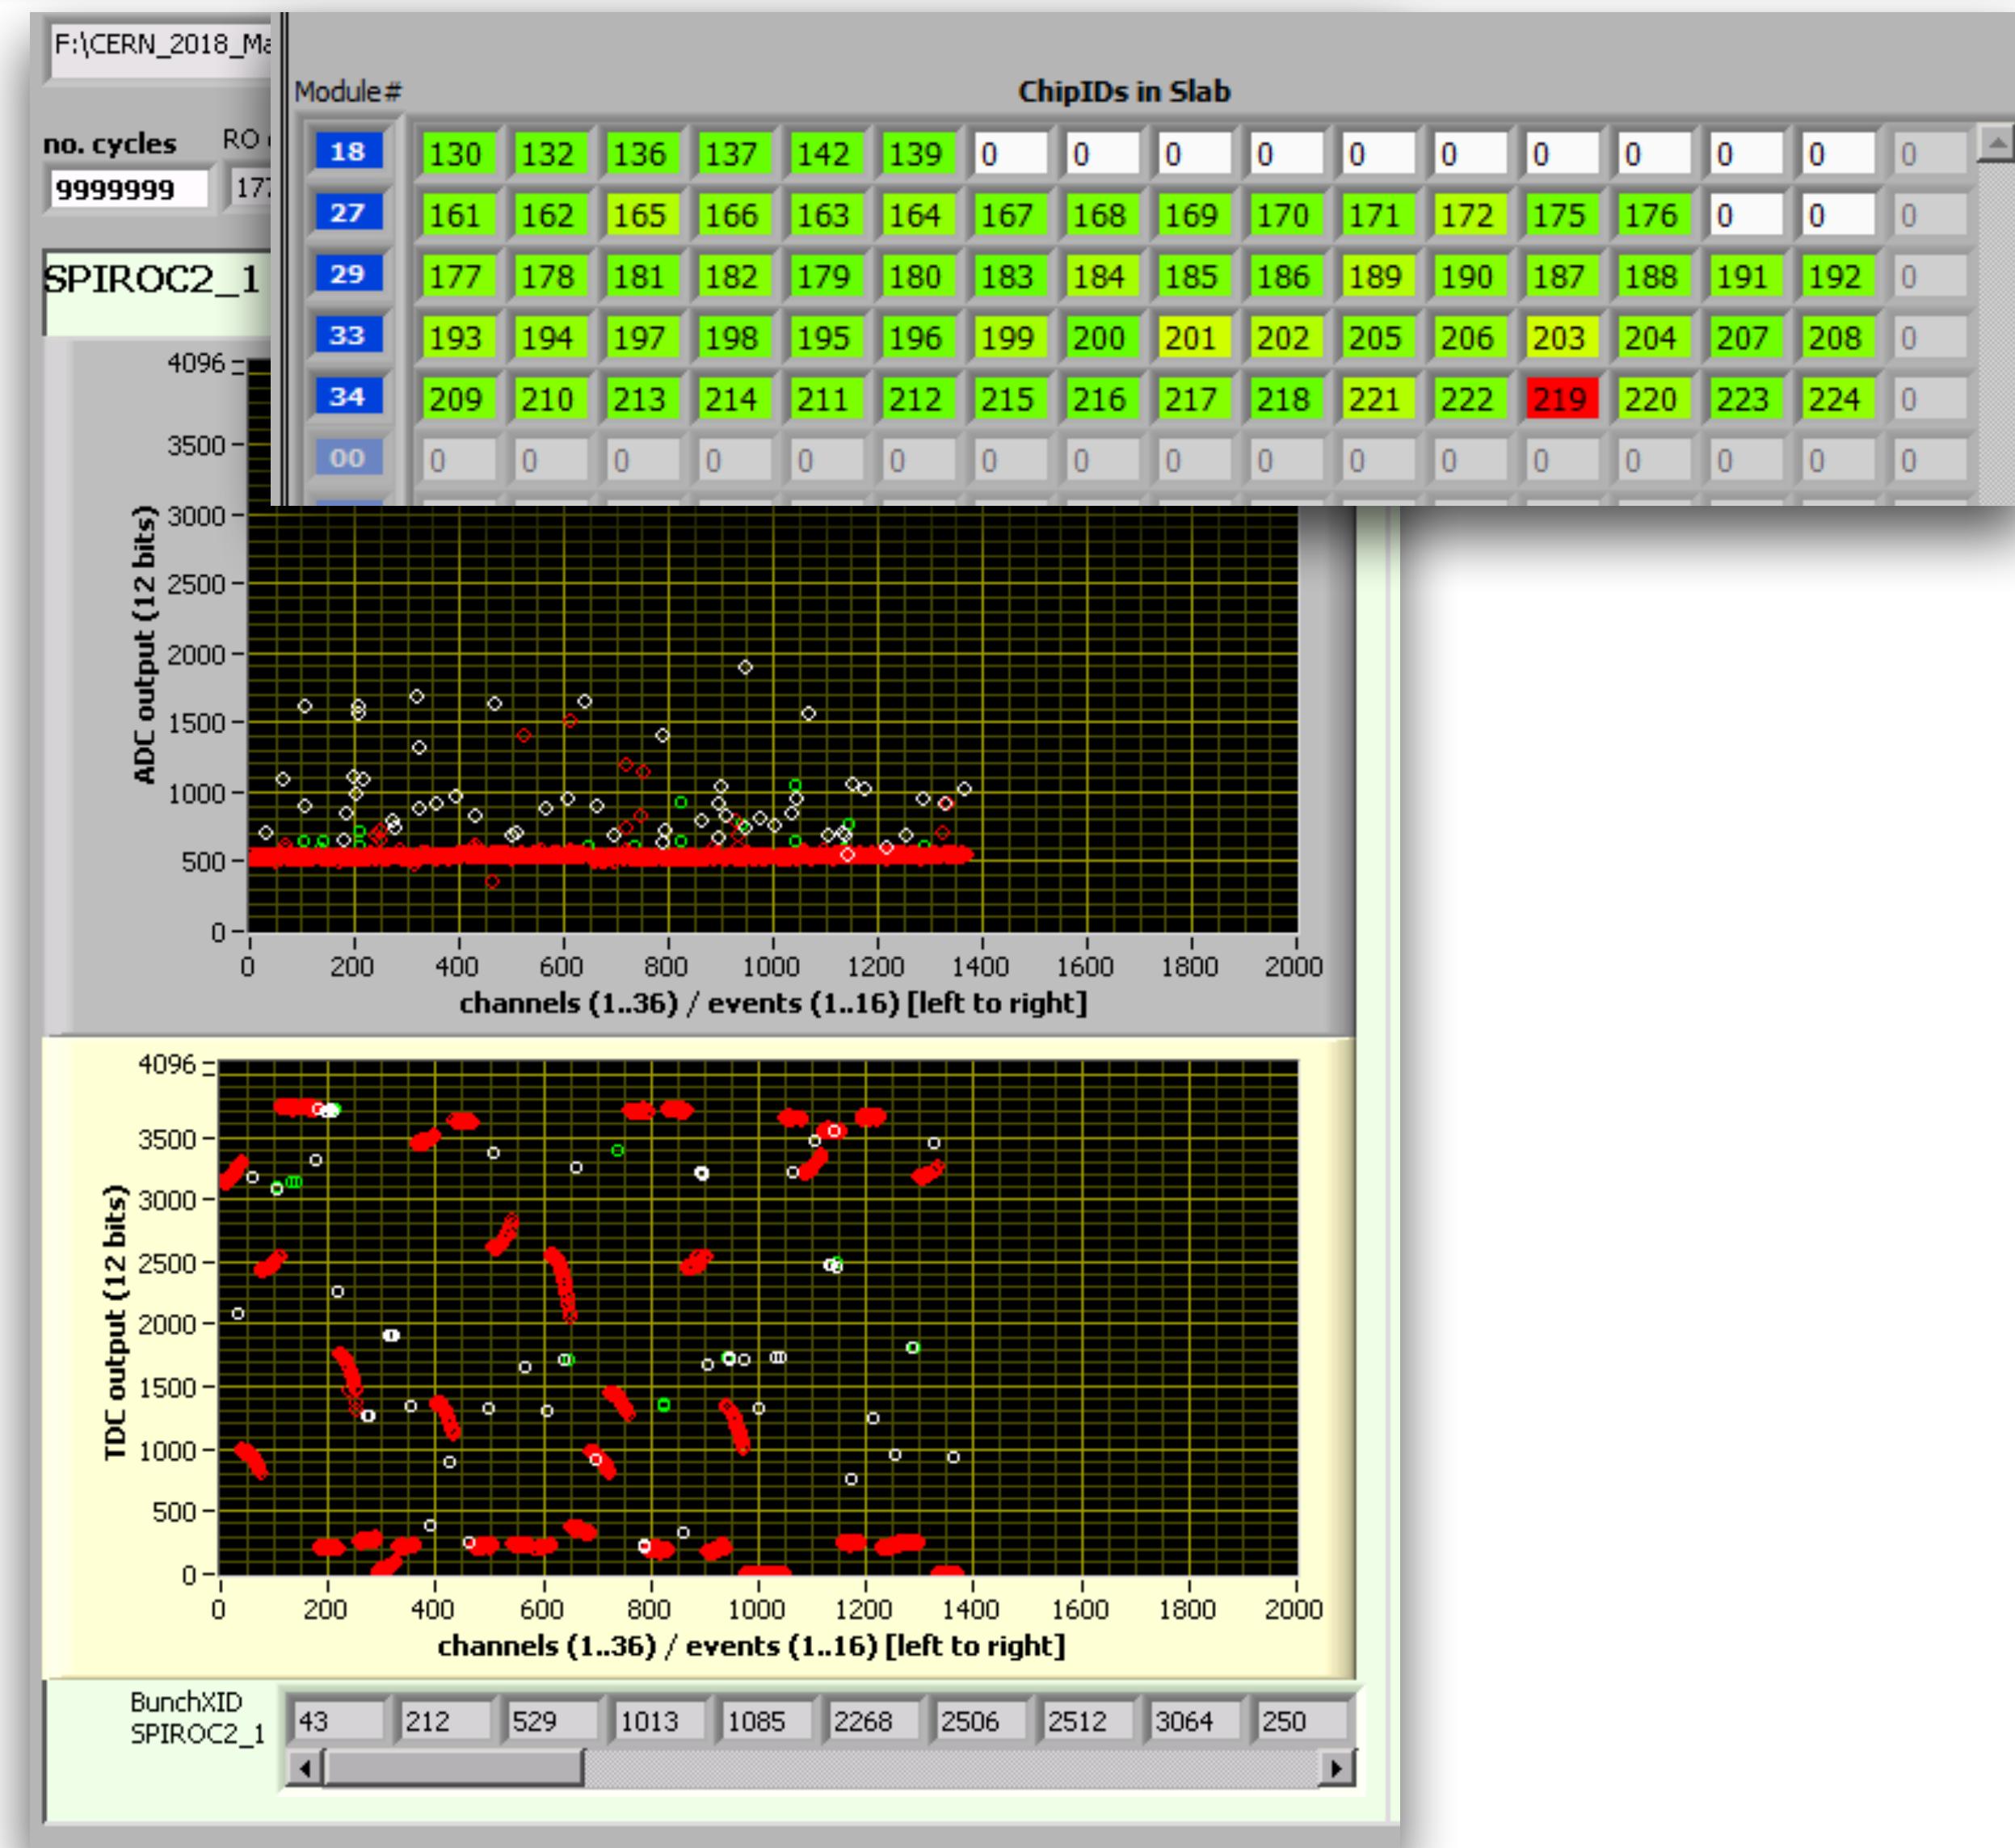

- **Muon:**
 - 40GeV and 120GeV scans with movable stage
 - at least 5000 hits per channel for time calibration and to cross-check MIP calibration
- **Electrons:**
 - 10GeV - 100GeV
- **Hadrons:**
 - 10GeV - 160GeV
- LED runs for gain calibration
- Running with and without power pulsing

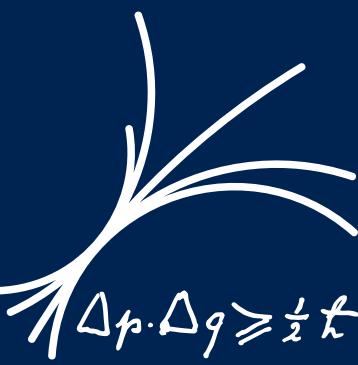

Monitoring

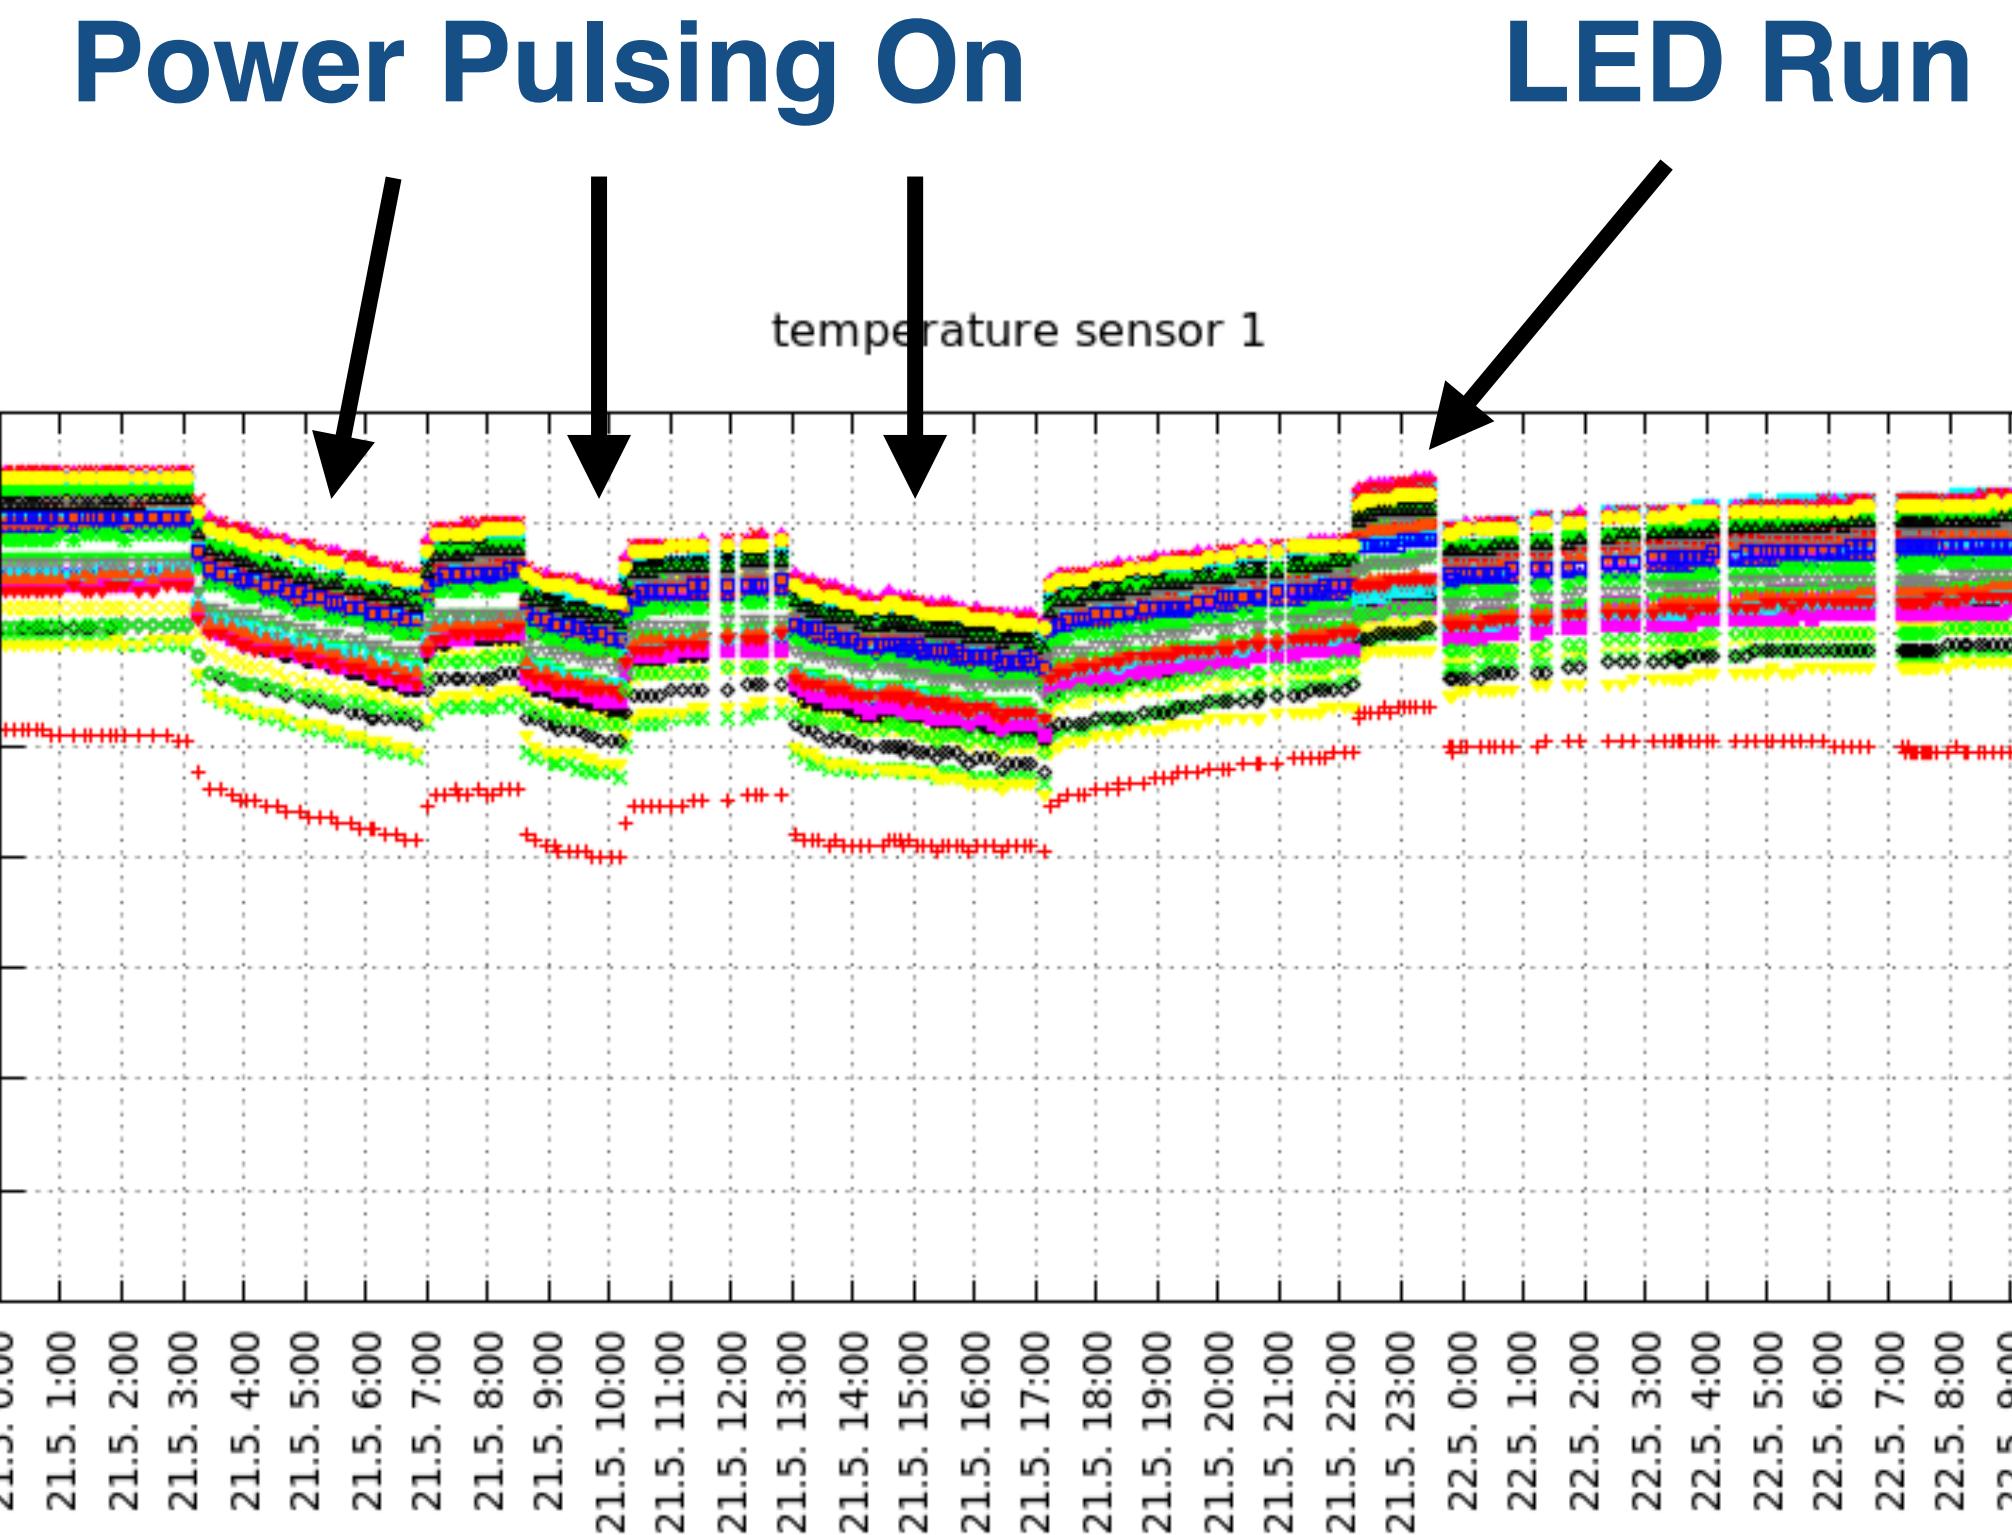

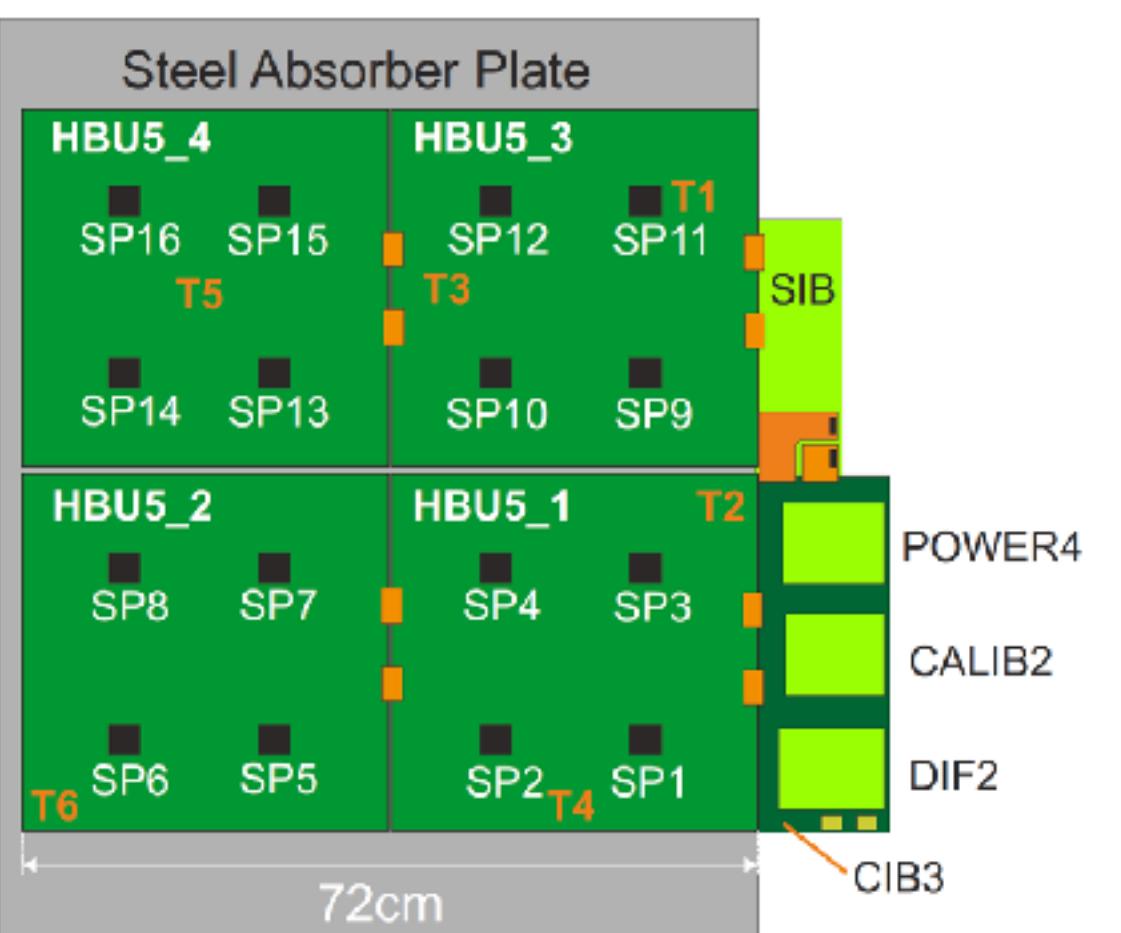

- **Labview:**
 - first impressions on data completeness

Monitoring

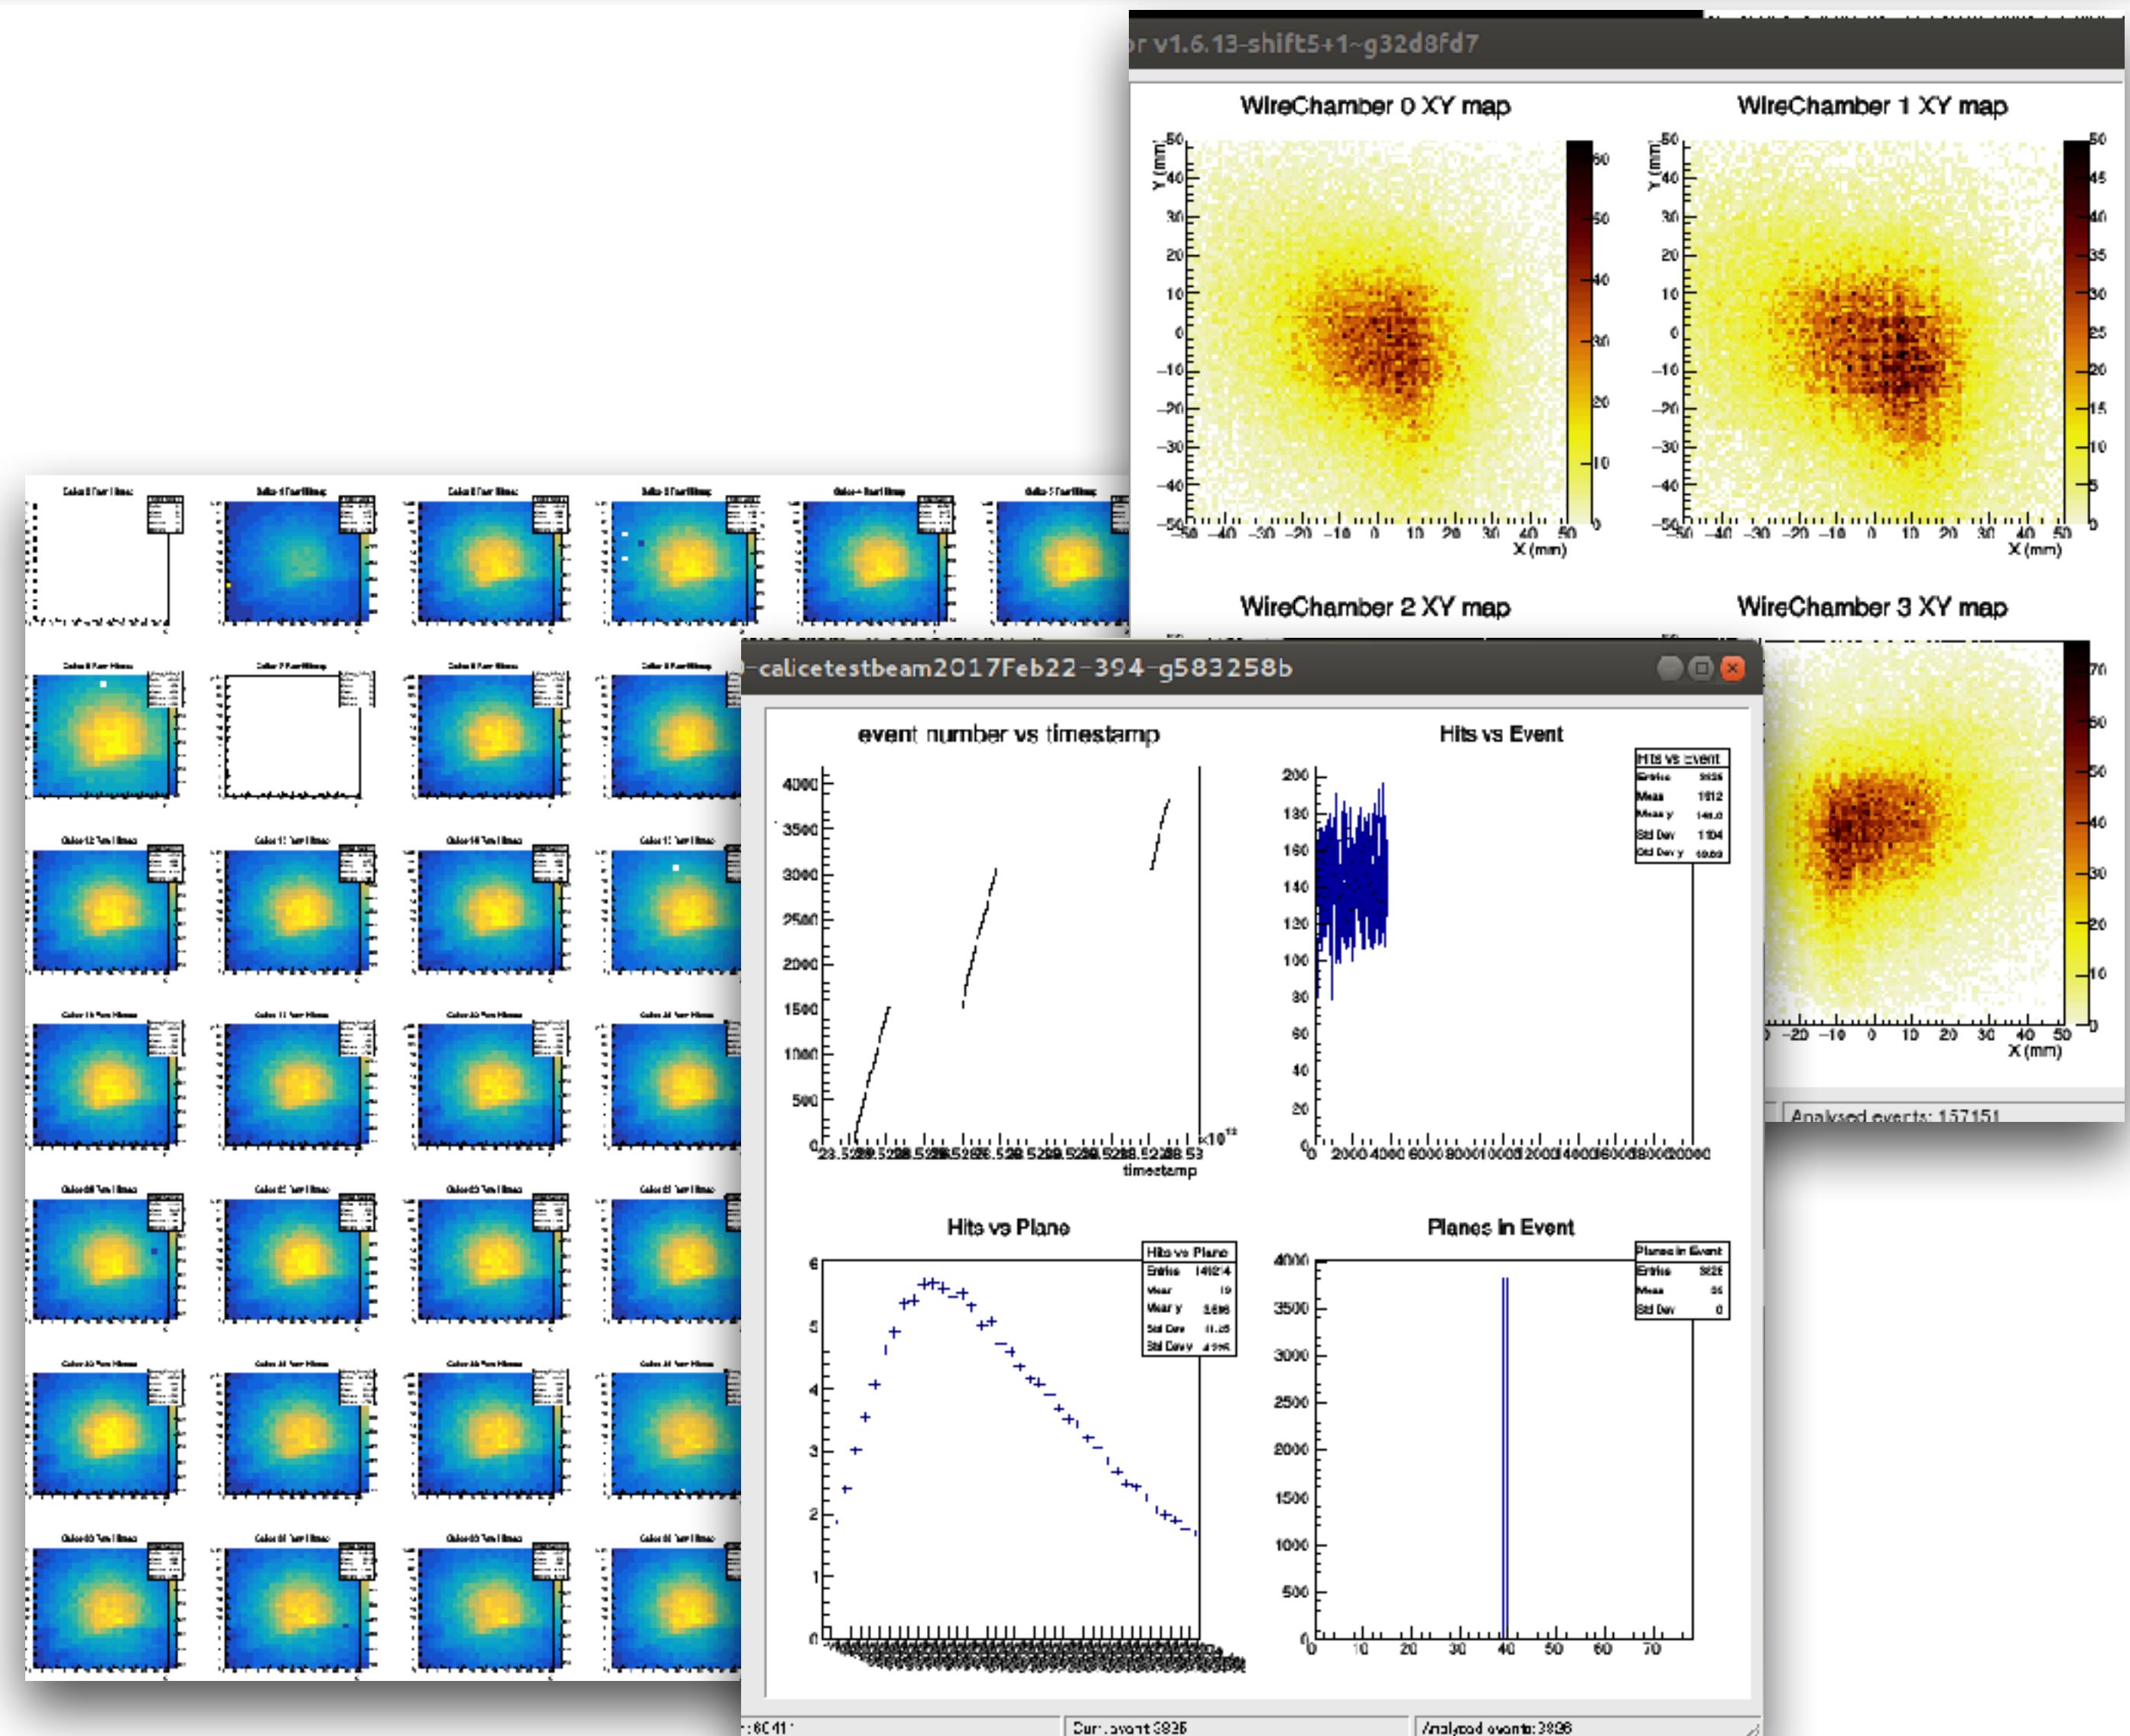

- Labview
- Temperature Monitoring:
 - temperature decrease for power pulsing
 - temperature increase for LED runs

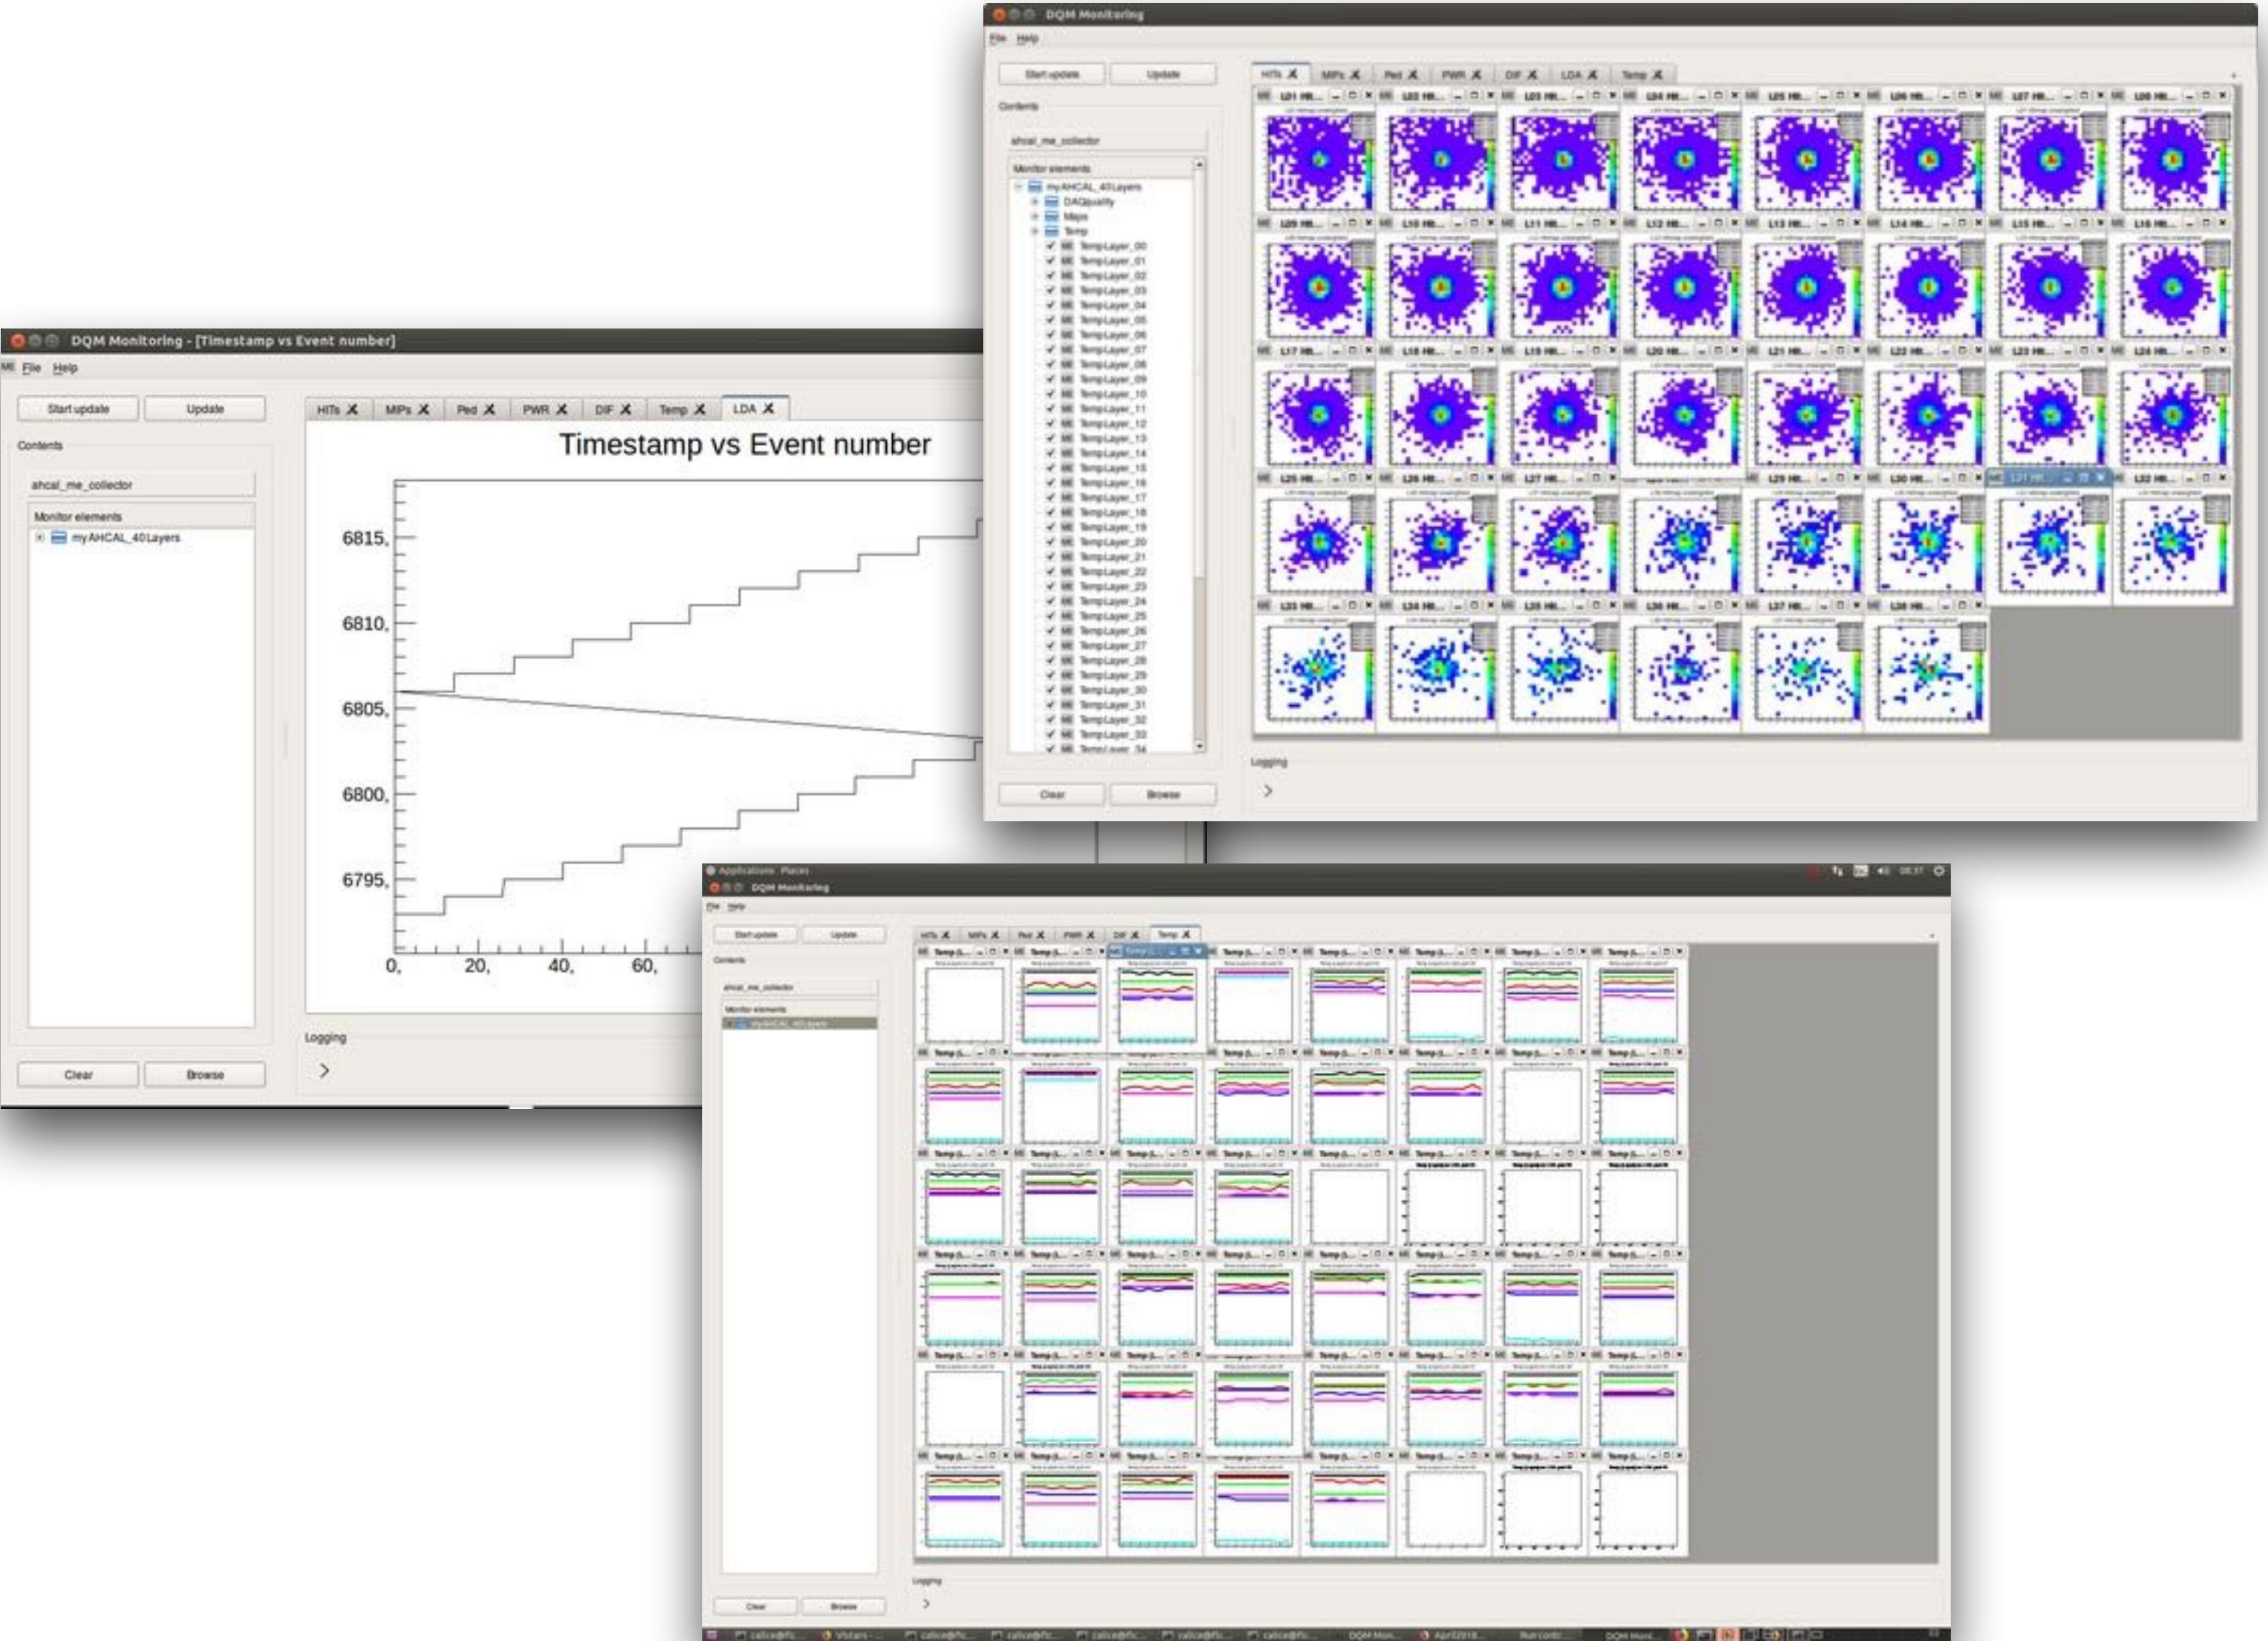

Monitoring

- **Labview**
- **Temperature Monitoring**
- **EUDAQ Monitors:**
 - wire chamber hit maps
 - AHCAL hit maps
 - low level plots

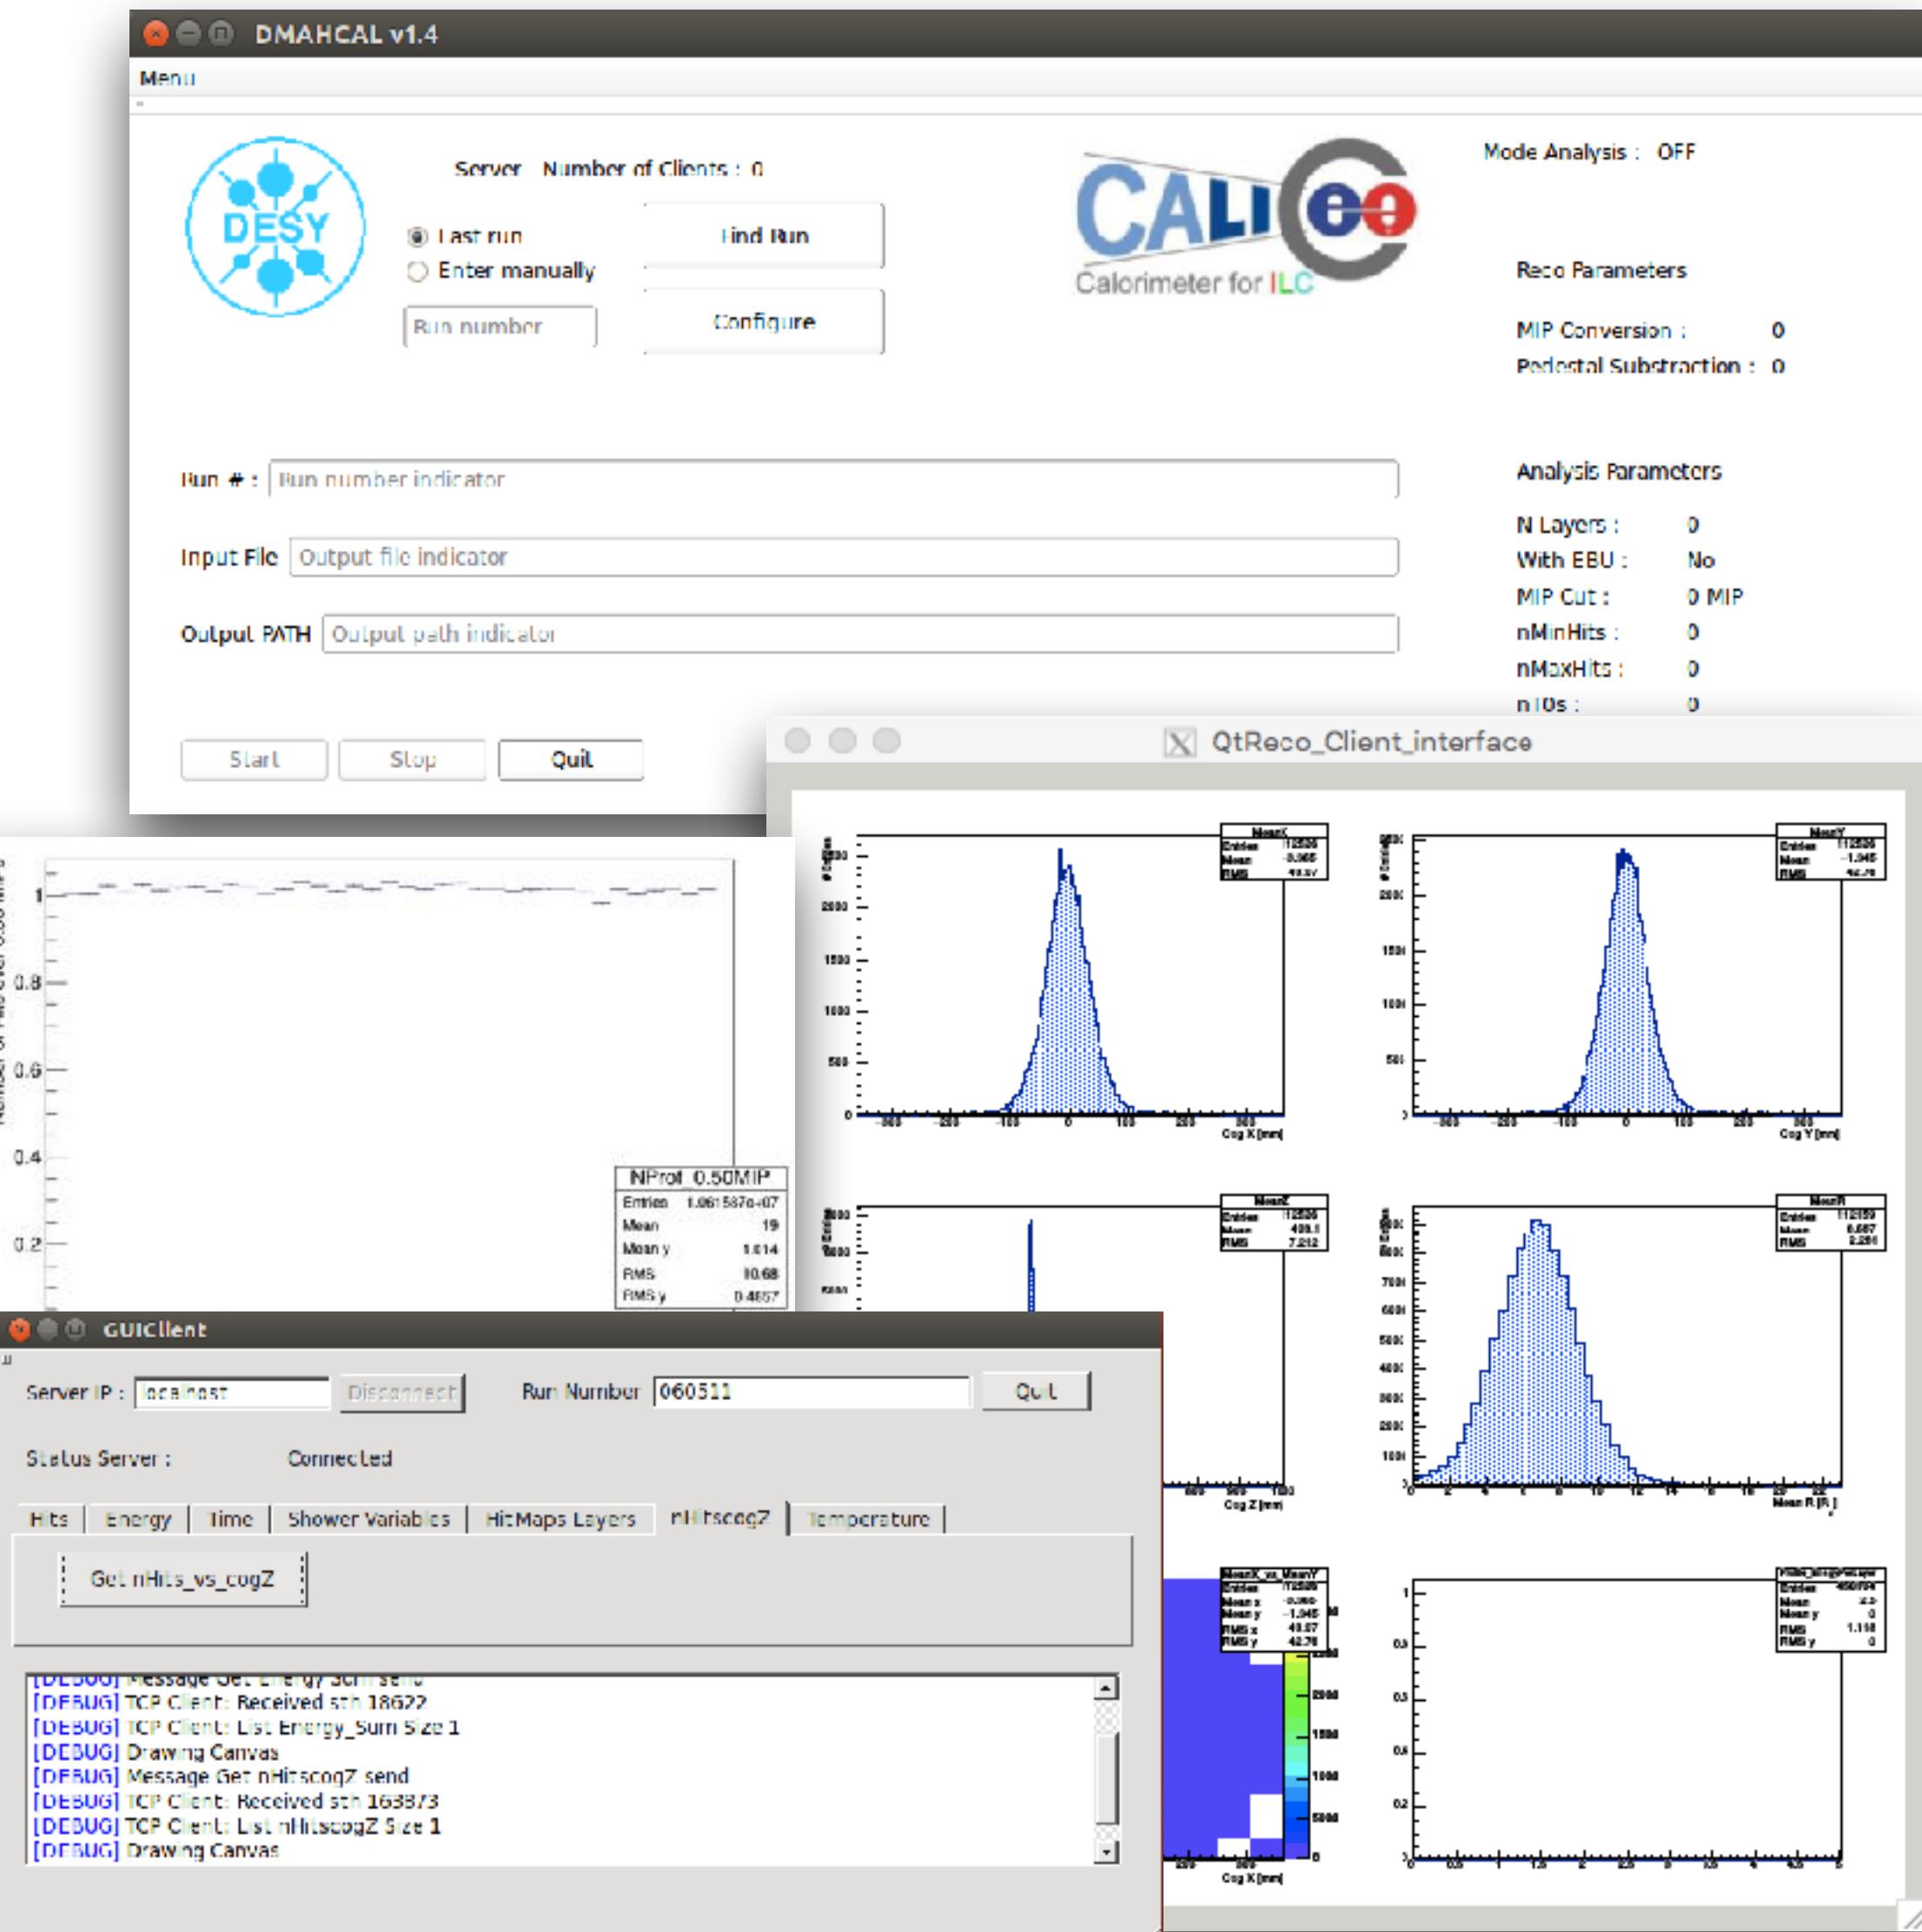

Monitoring

- Labview
- Temperature Monitoring
- EUDAQ Monitors
- DQM4HEP:
 - online monitor
 - hit maps, temperature, ...
 - more to be implemented

Monitoring

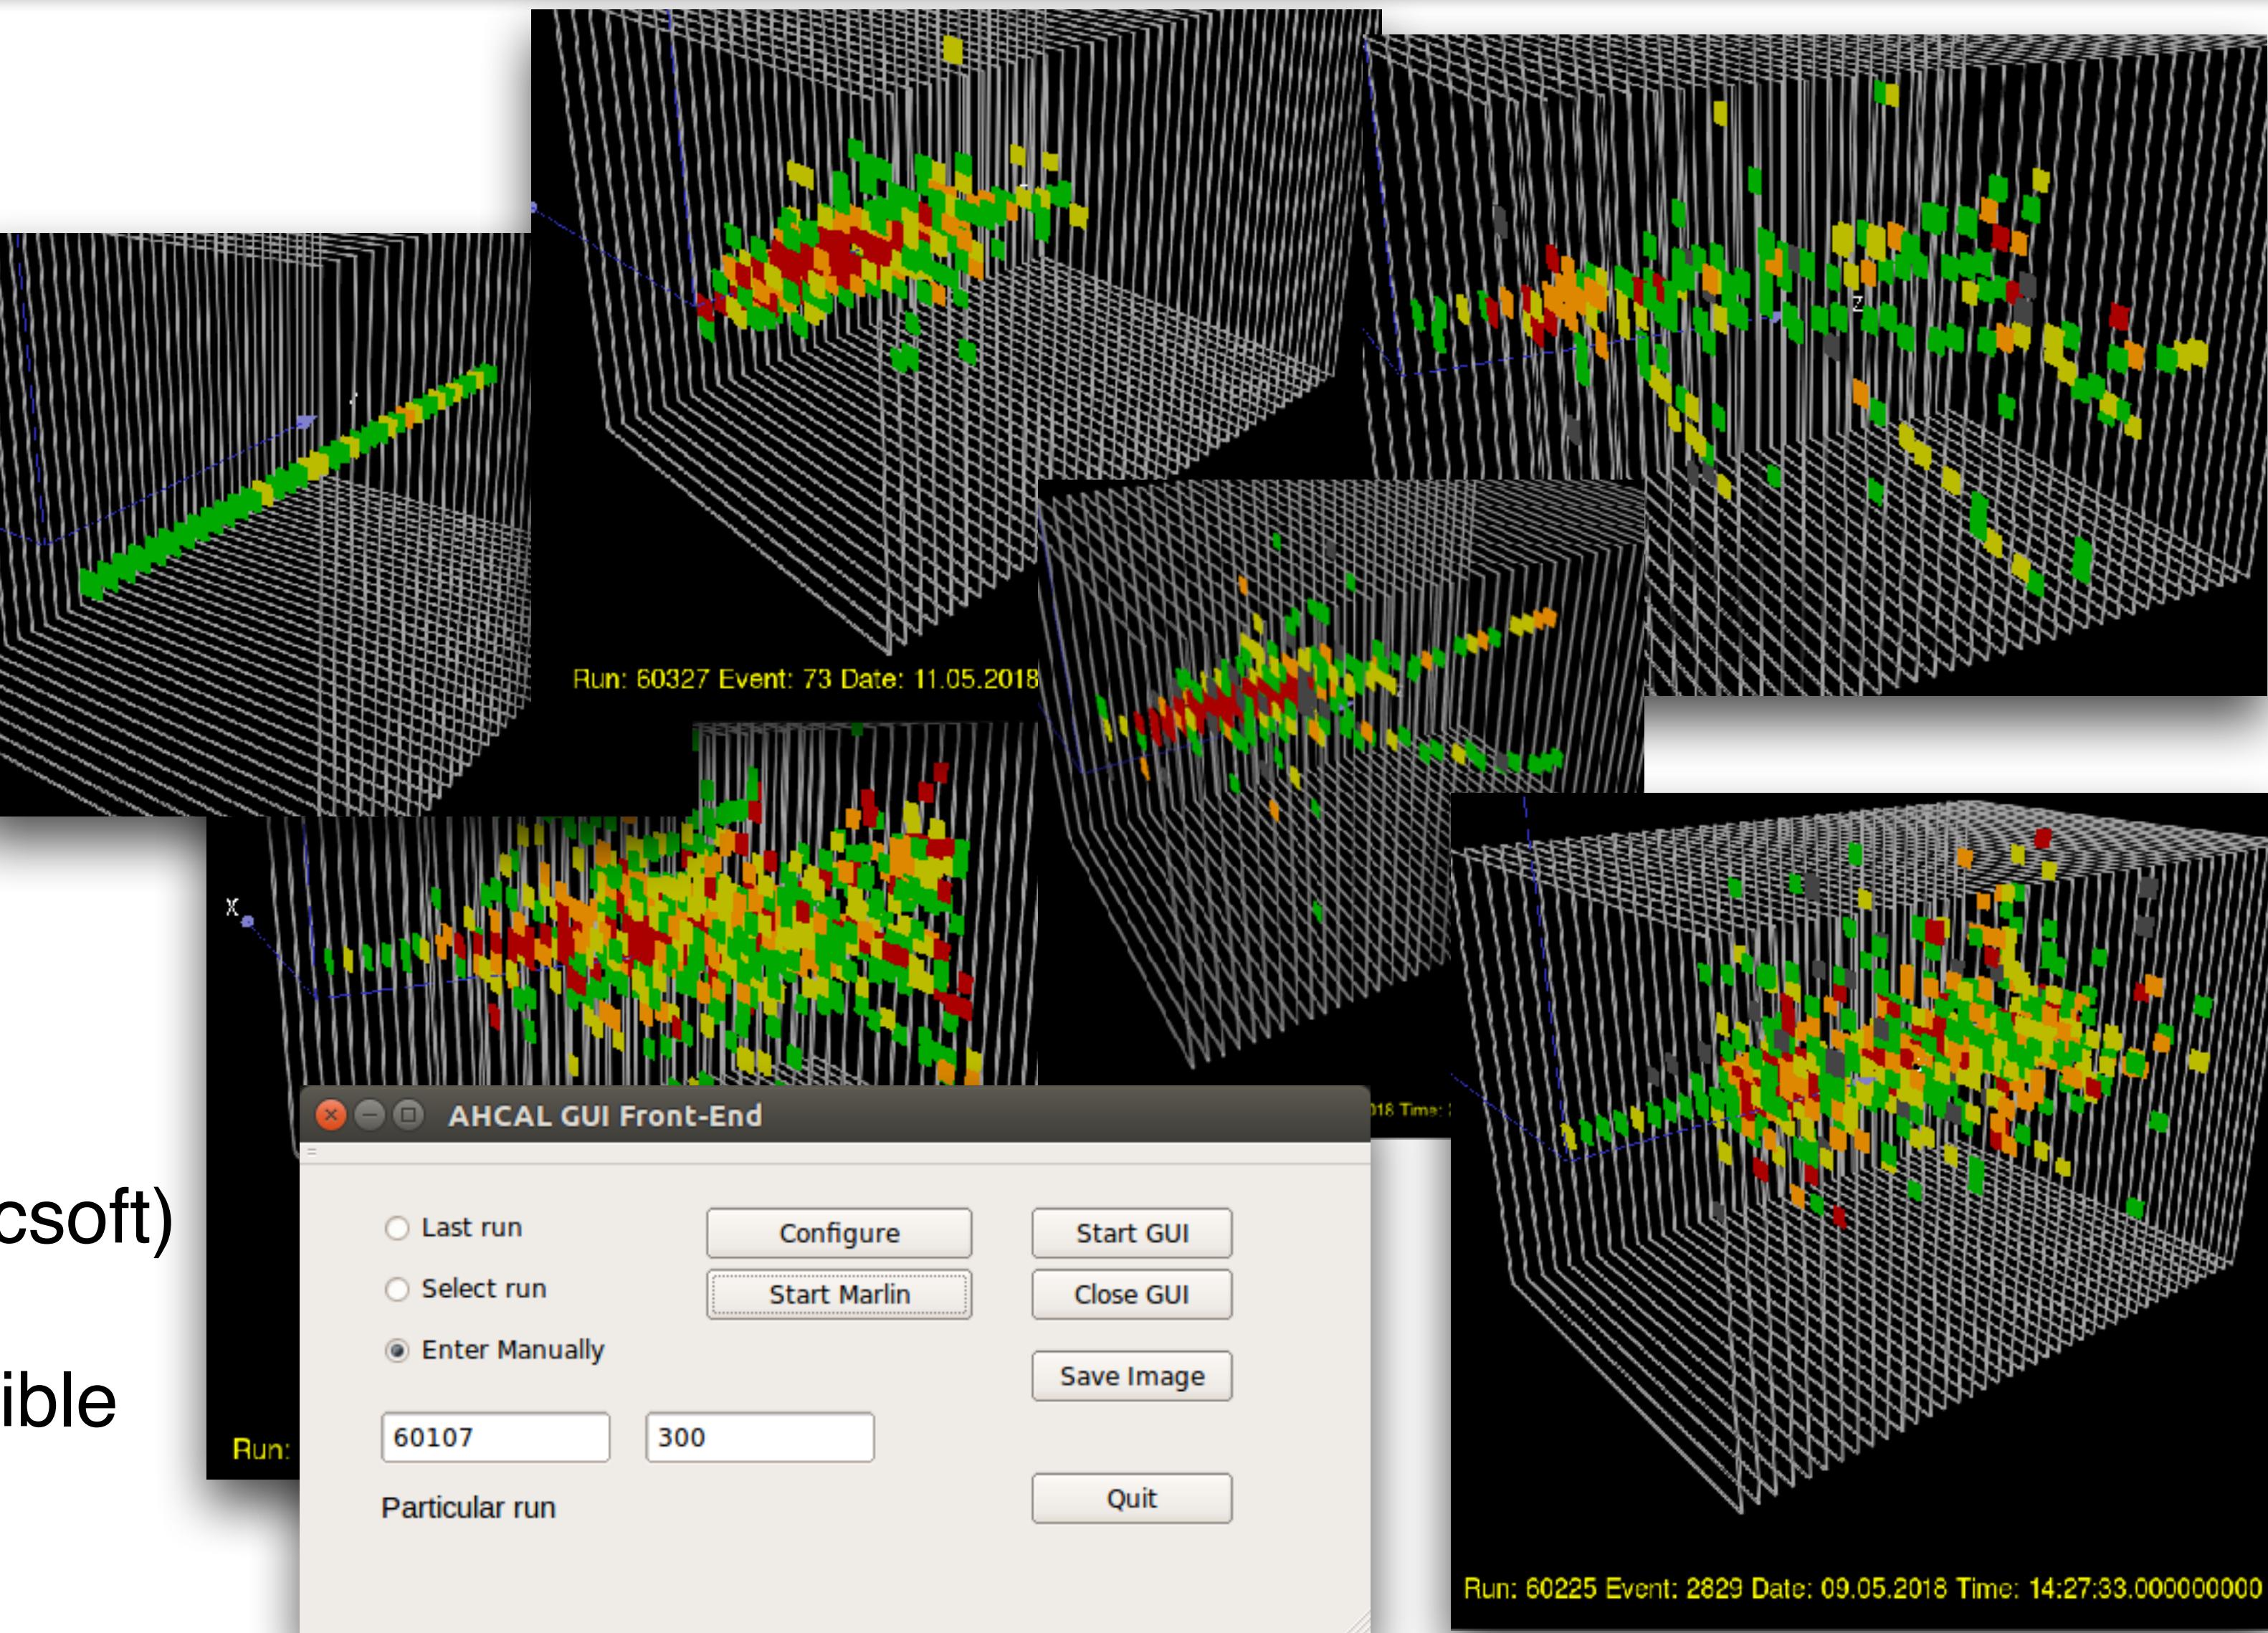

- **Labview**
- **Temperature Monitoring**
- **EUDAQ Monitors**
- **DQM4HEP**
- **Quasi-Online Monitor:**
 - fast reconstruction of files (even while data taking)
 - access to full root tree
 - easy GUI Access to many plots as:
number of hits distributions, energy distributions,
hit maps, shower variables, time distribution, ...

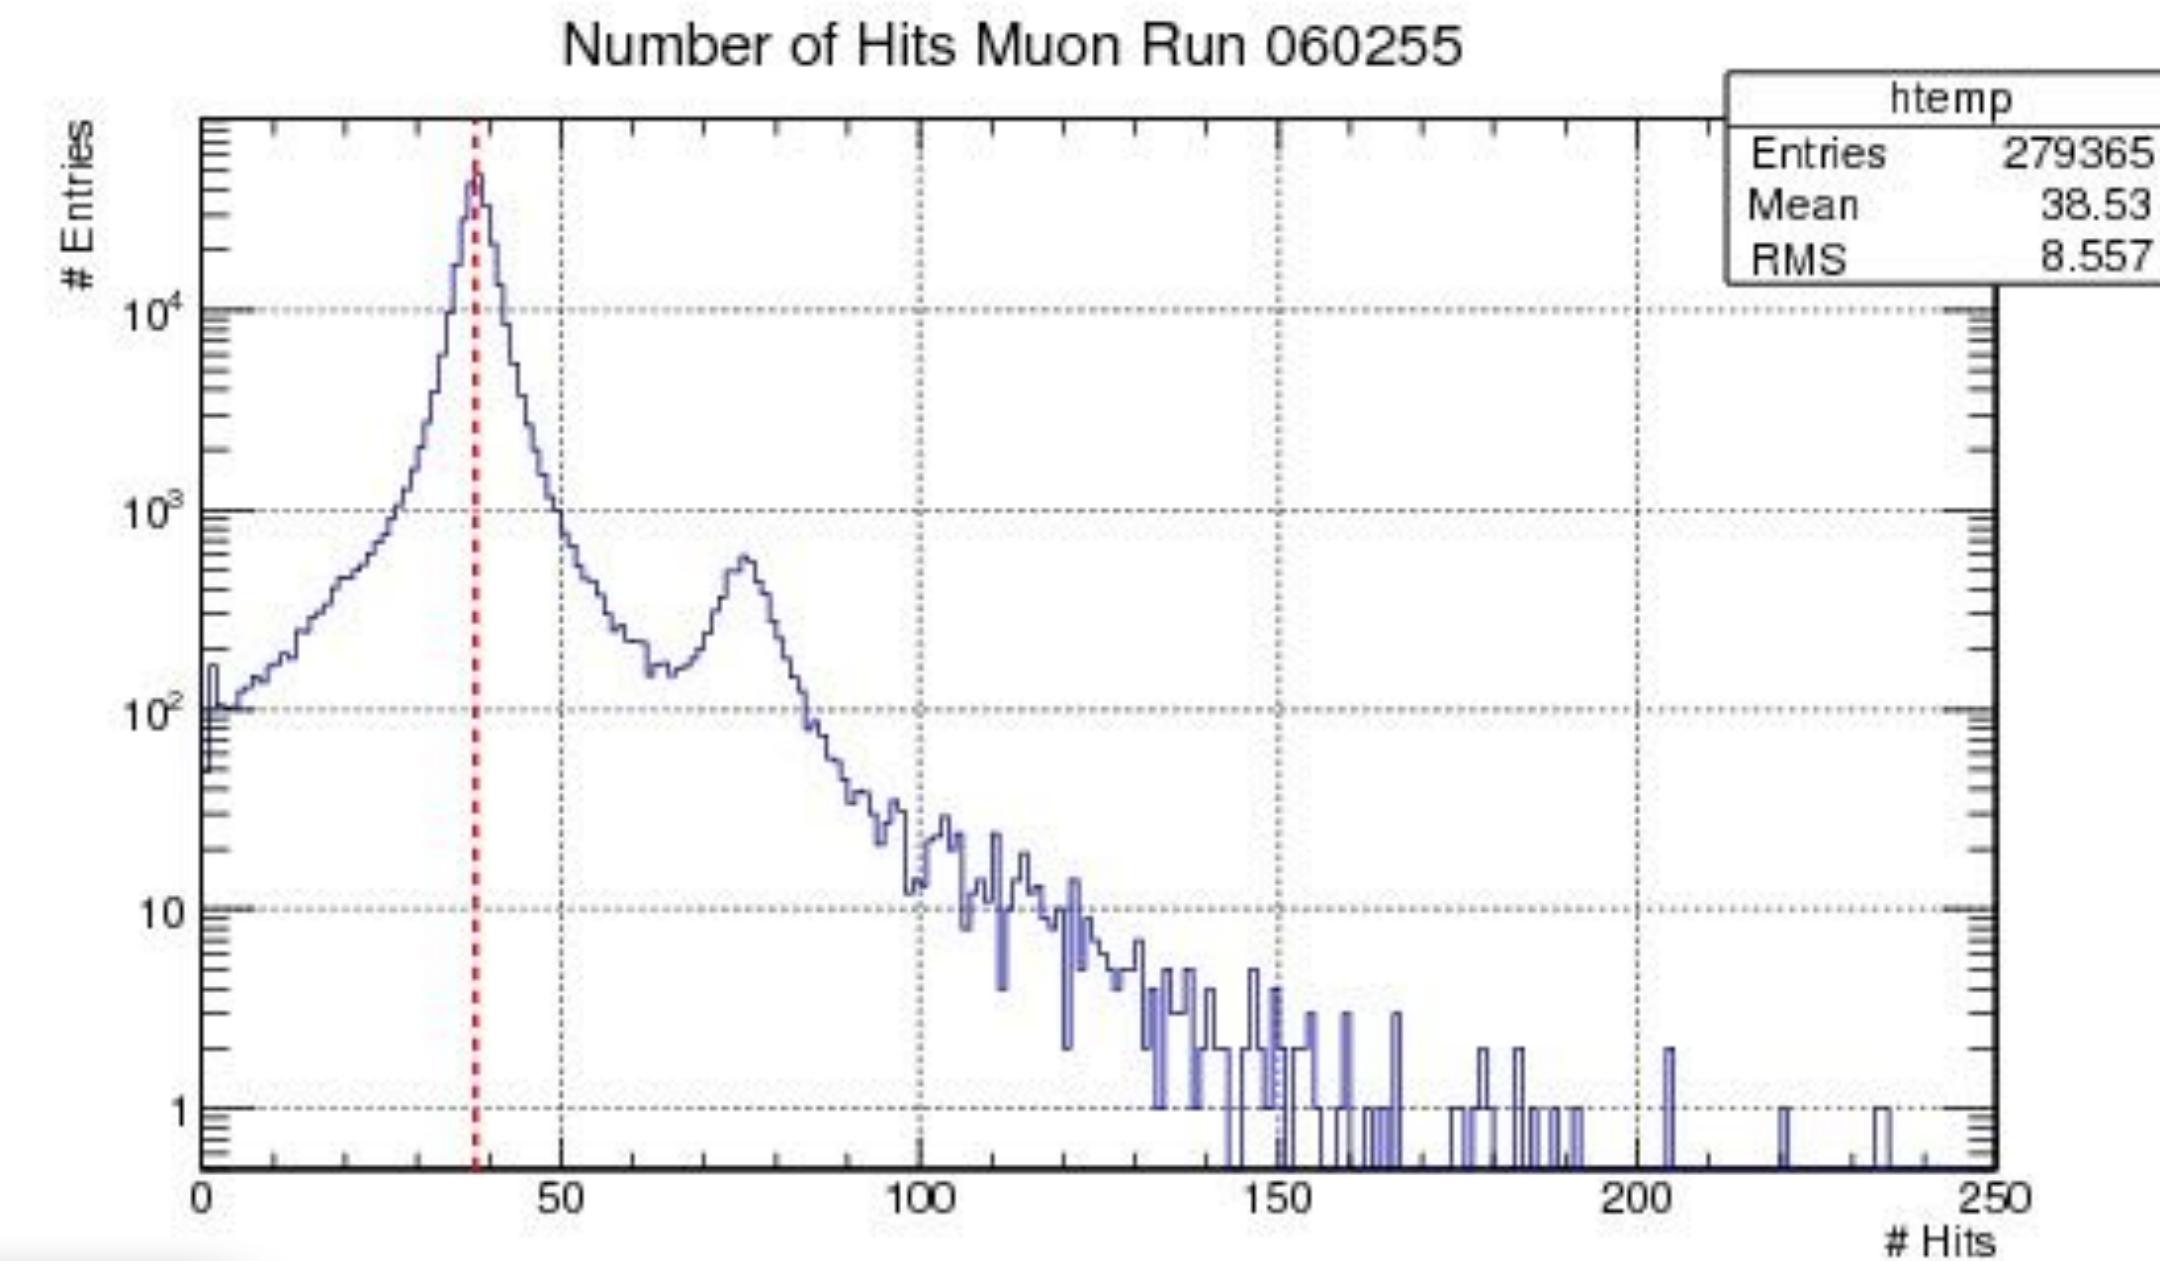

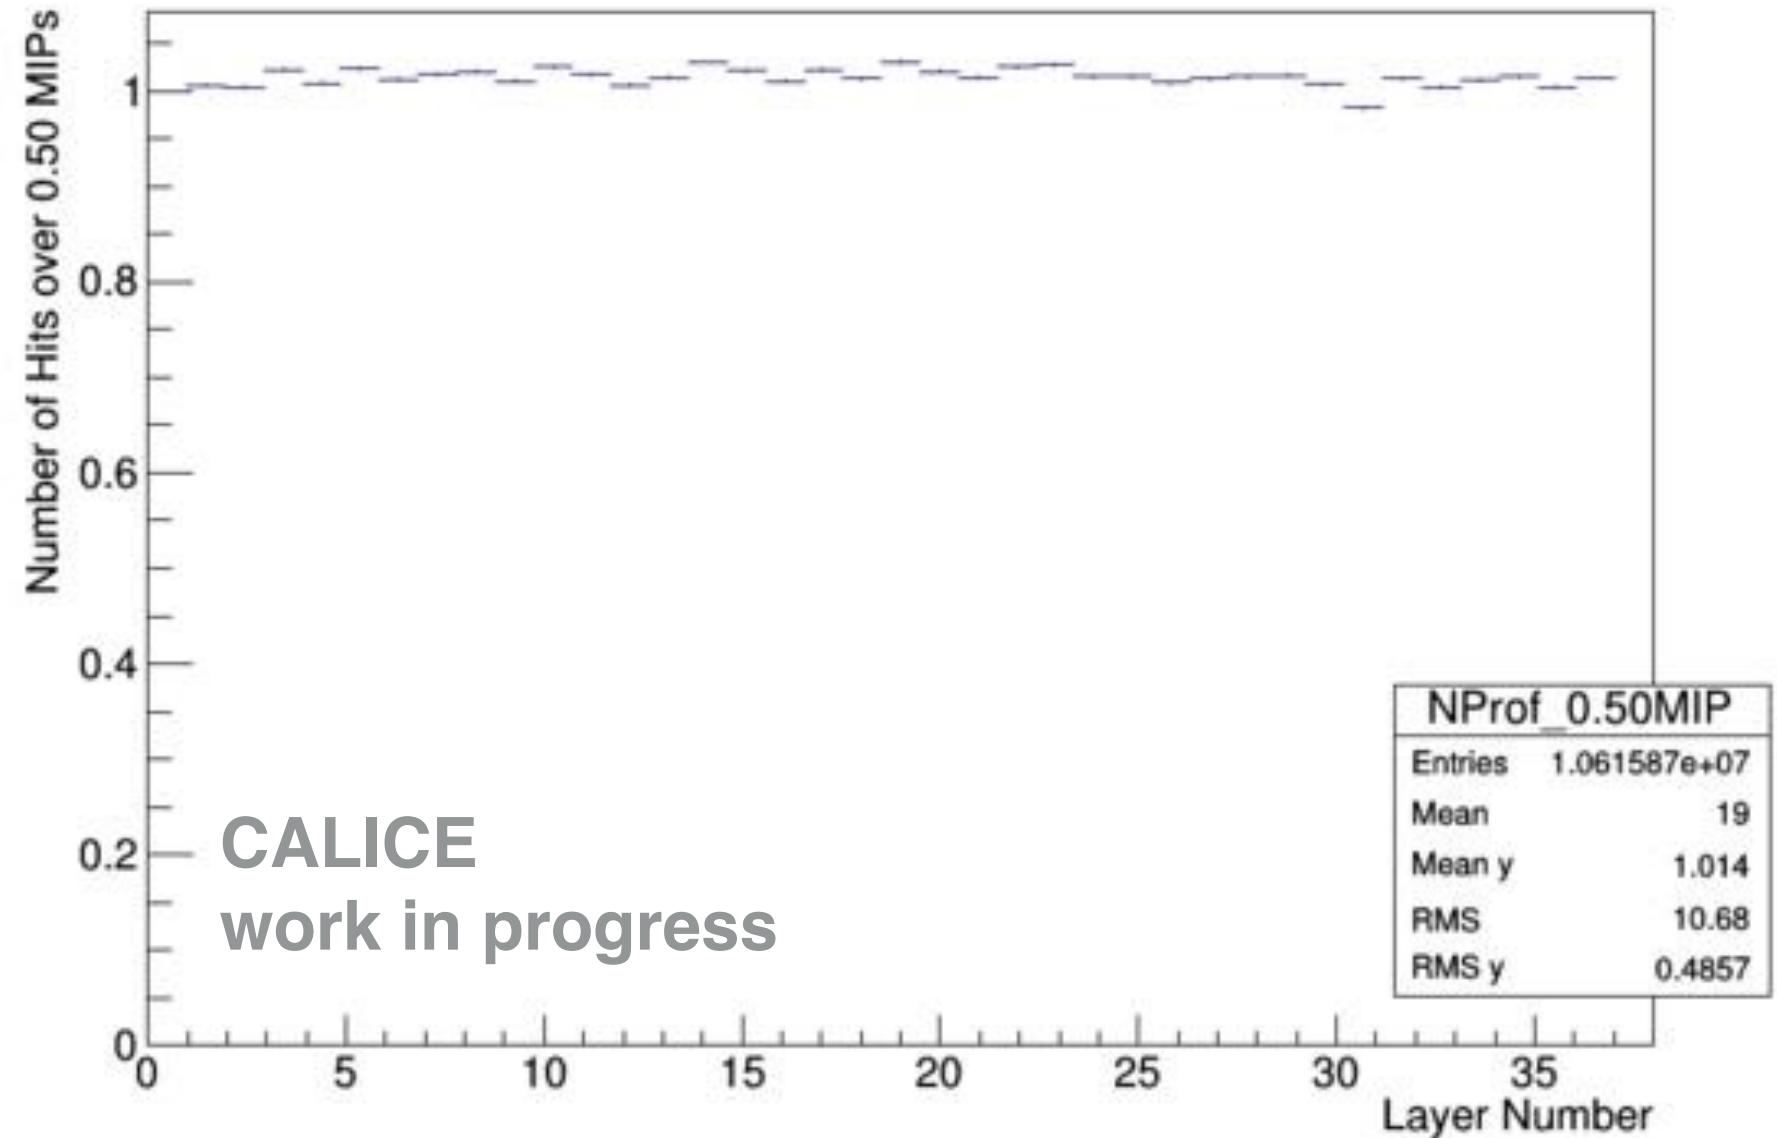

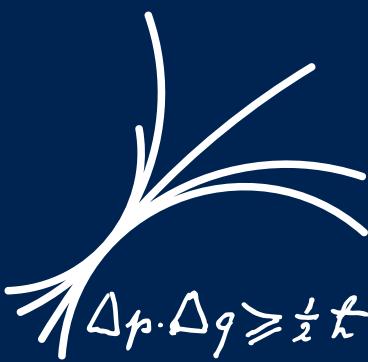

Monitoring

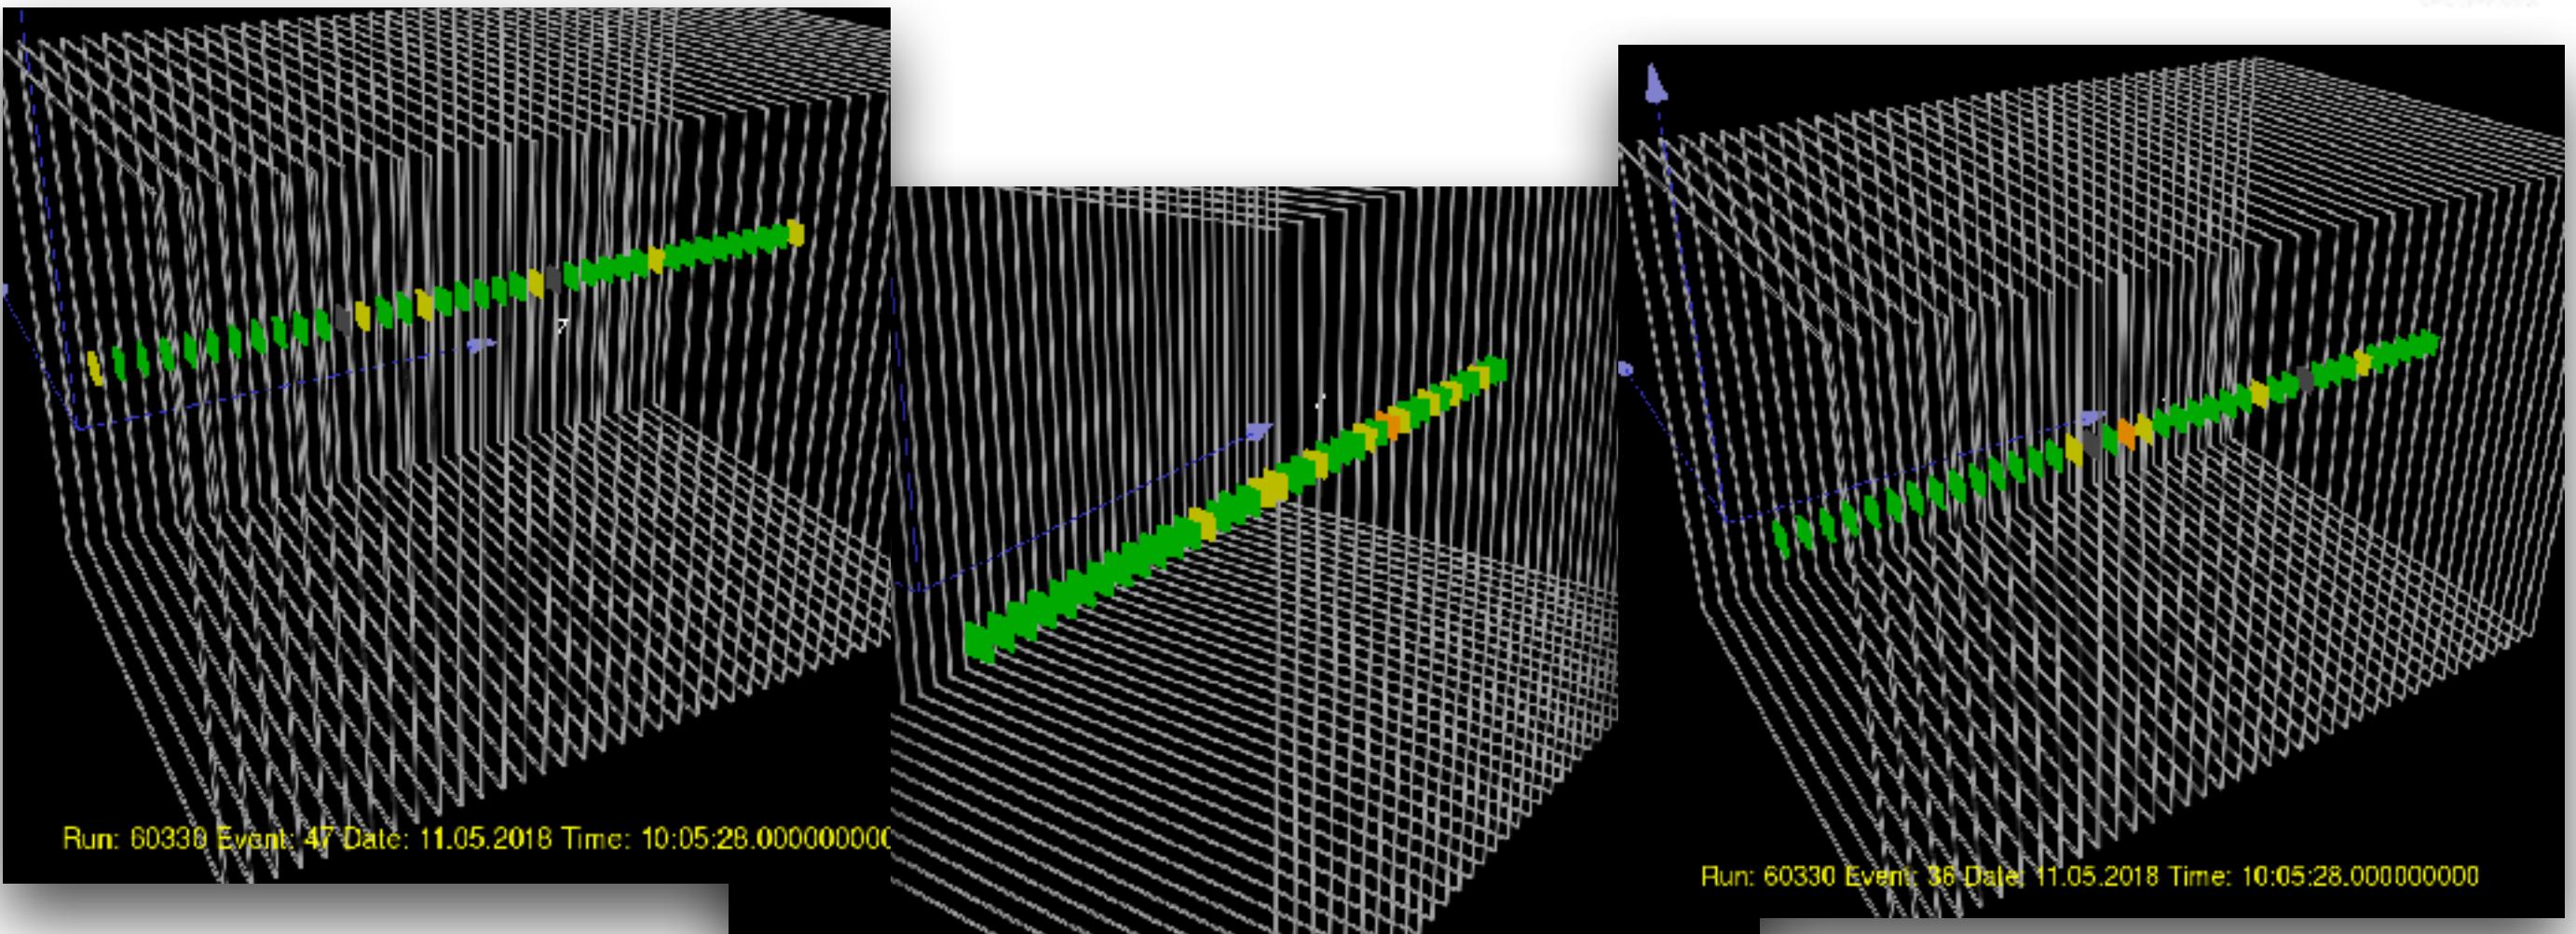

- **Labview**
- **Temperature Monitoring**
- **EUDAQ Monitors**
- **DQM4HEP**
- **Quasi-Online Monitor**
- **Event Display:**
 - easy to use GUI
 - based on CED (C event display, ilcsoft)
 - runs on reconstructed slcio files
 - energy or time color scheme possible

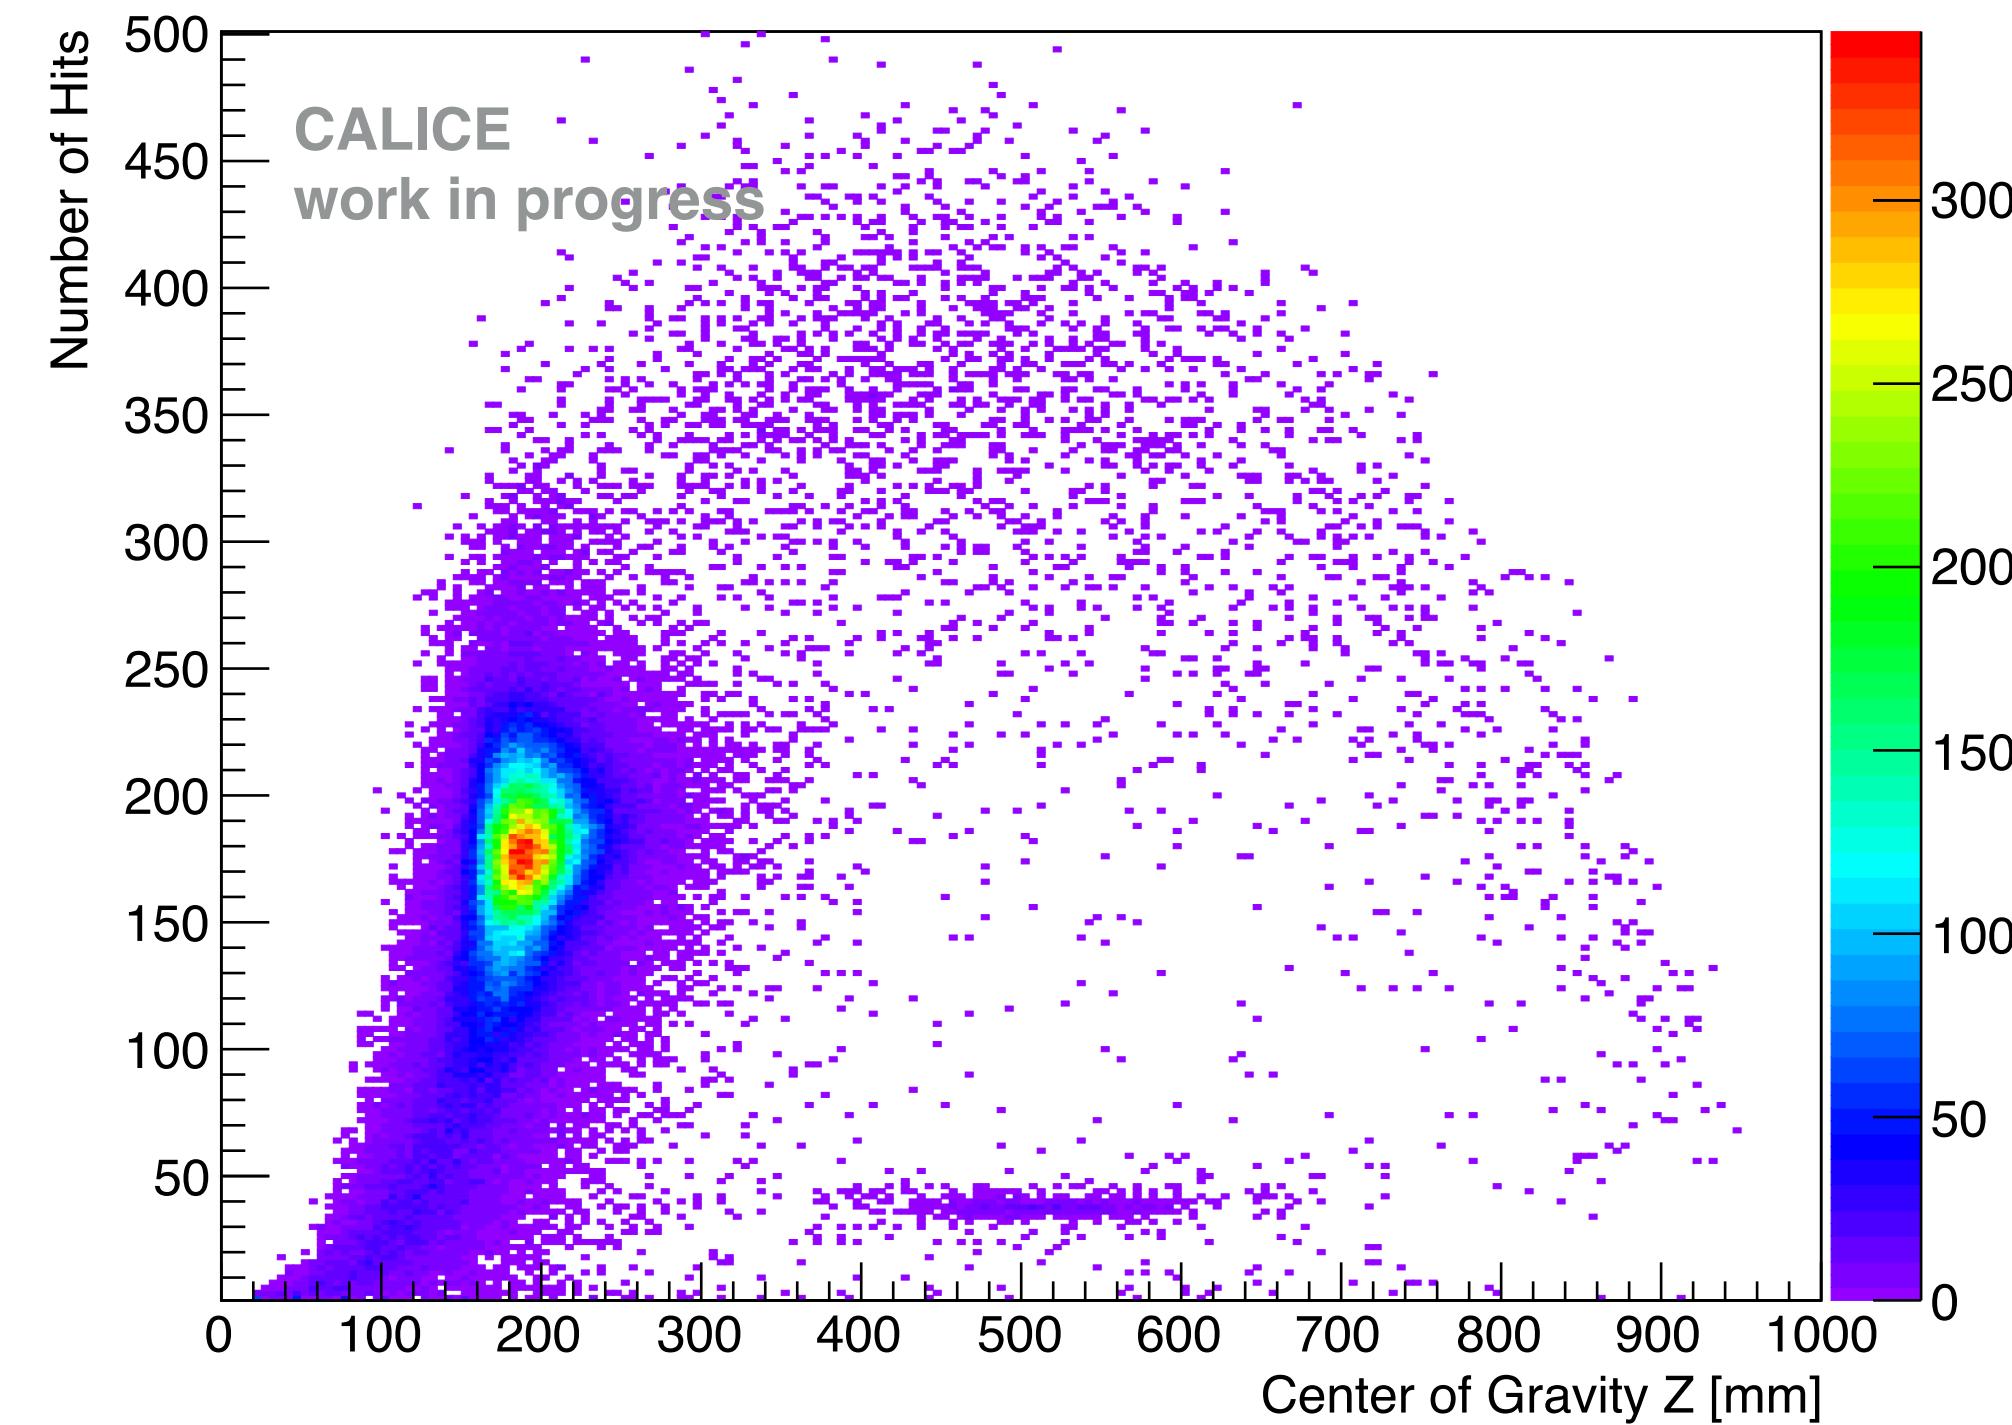

Muon Beam

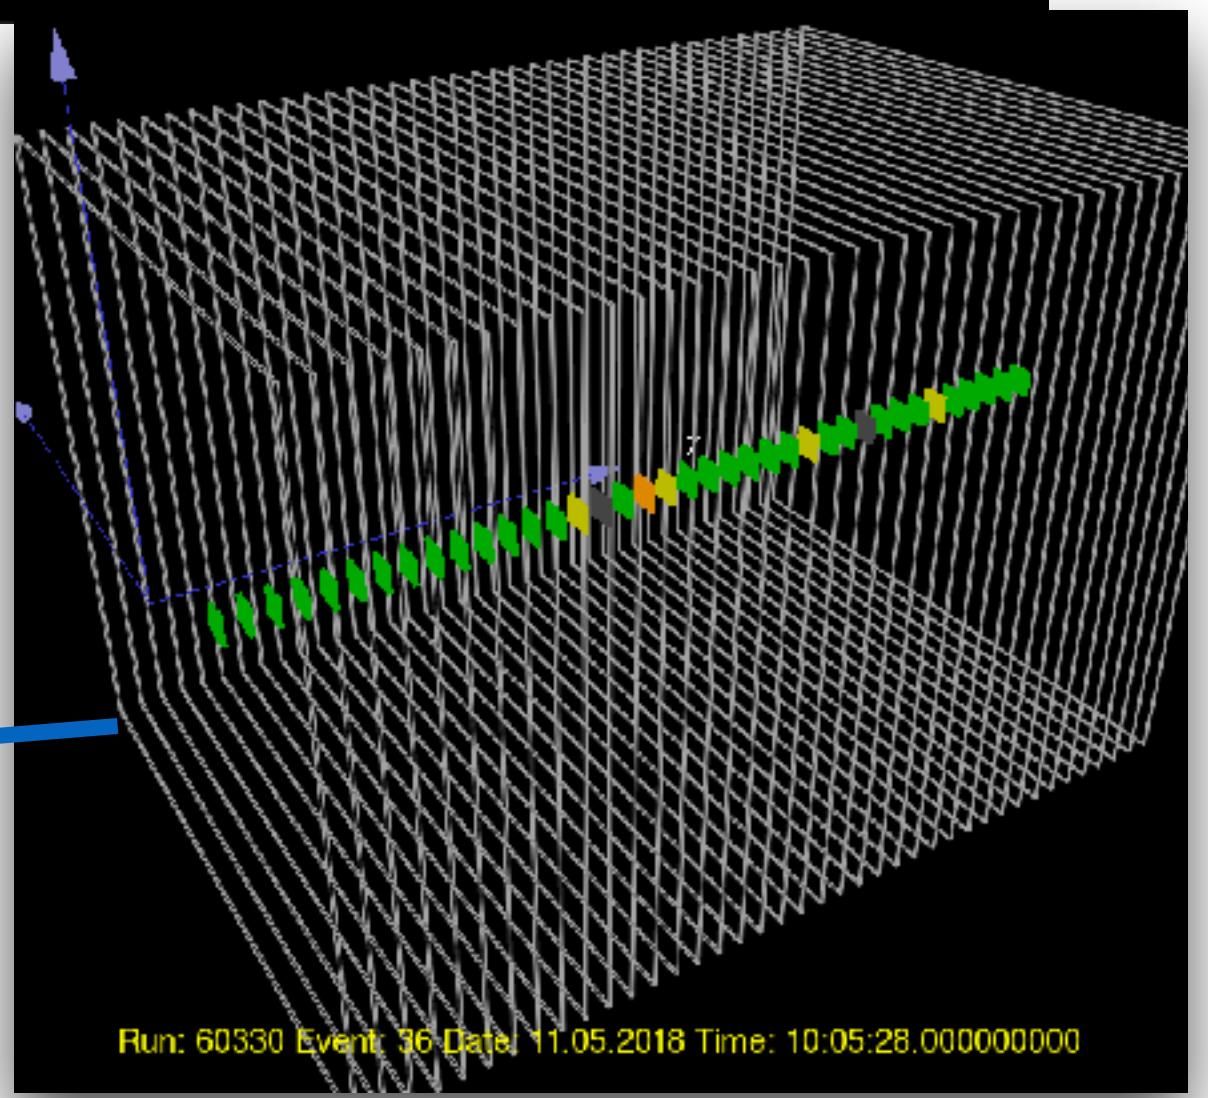

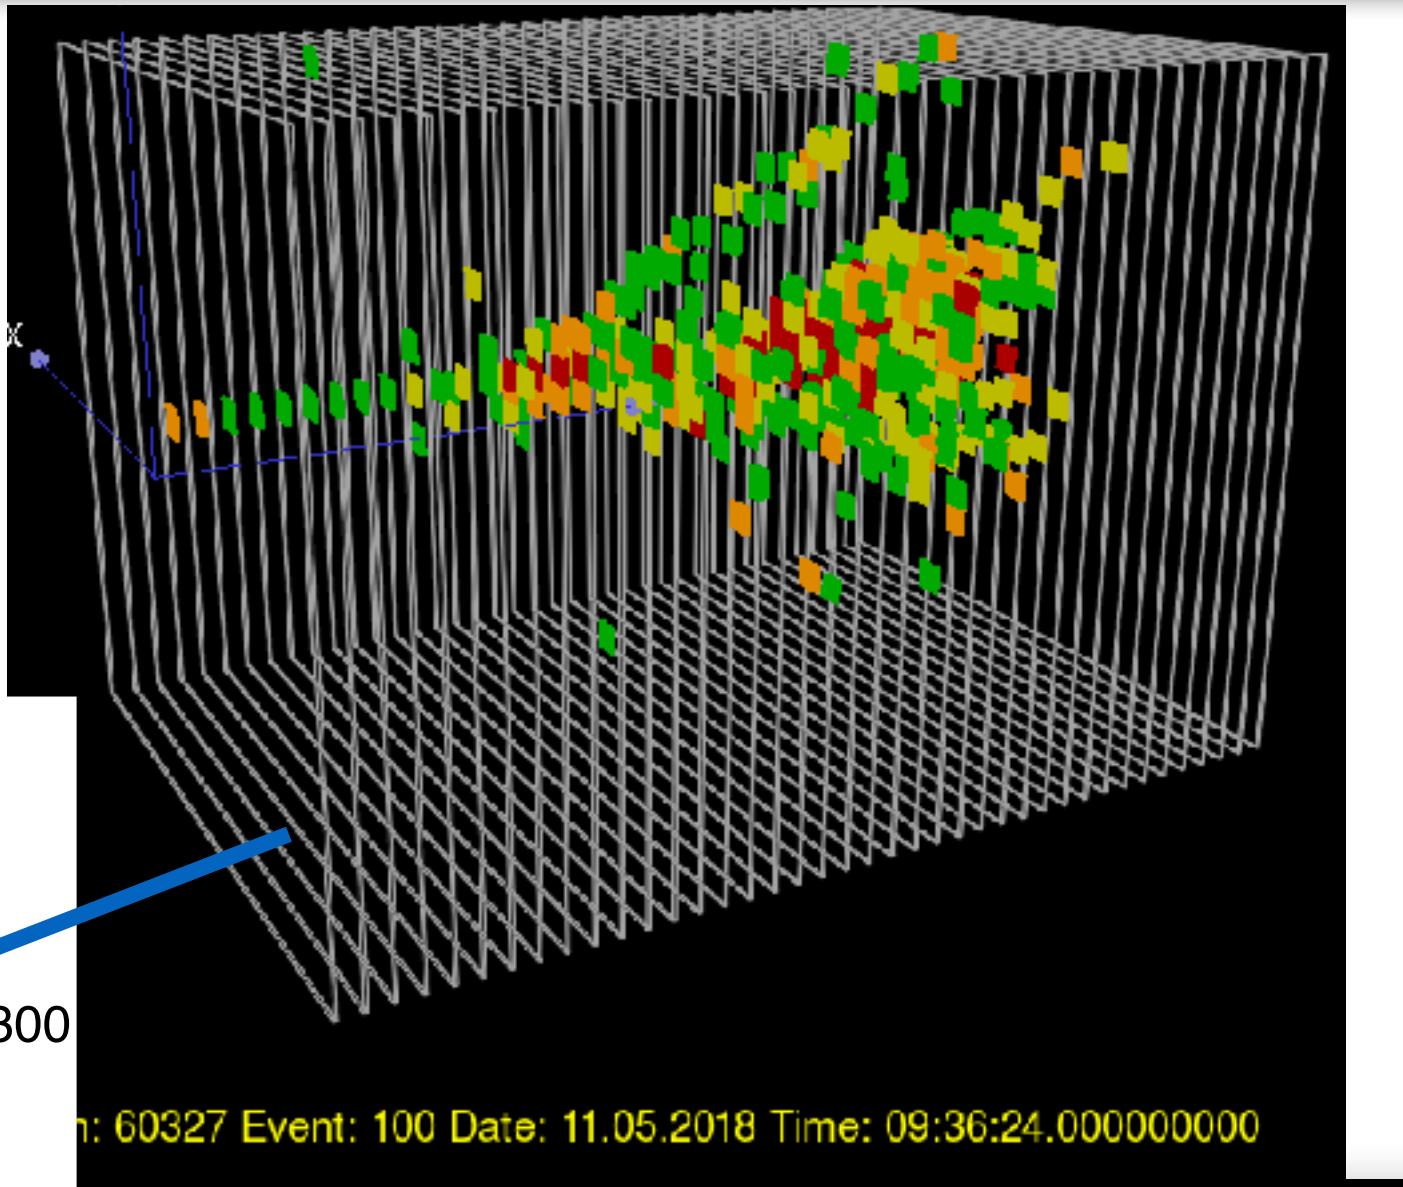

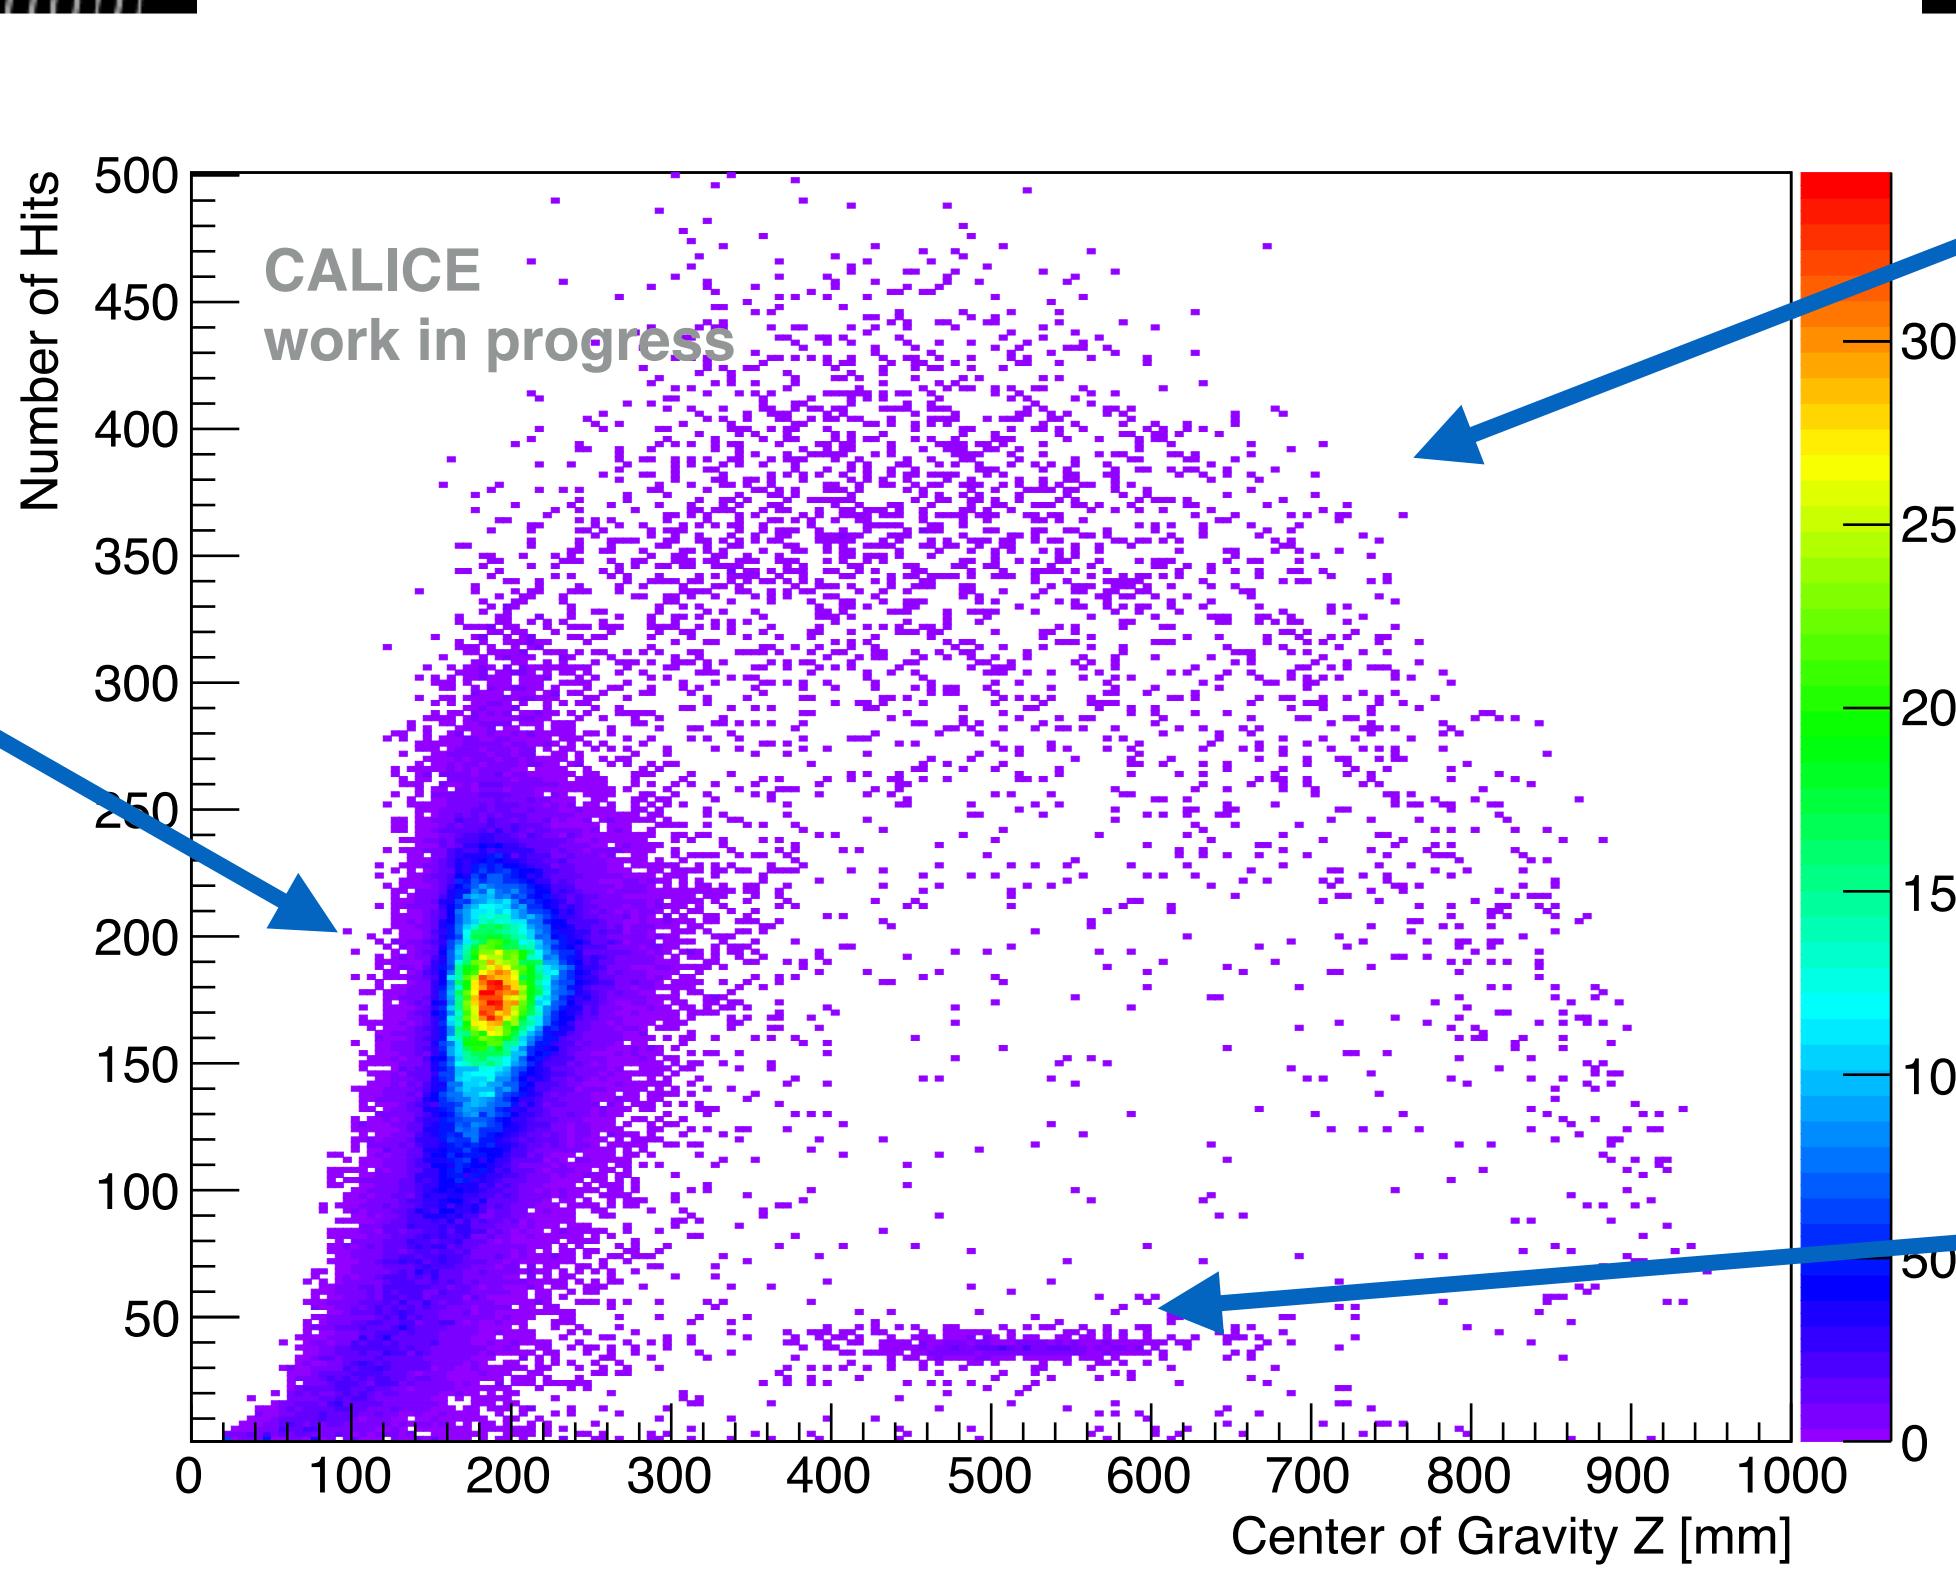

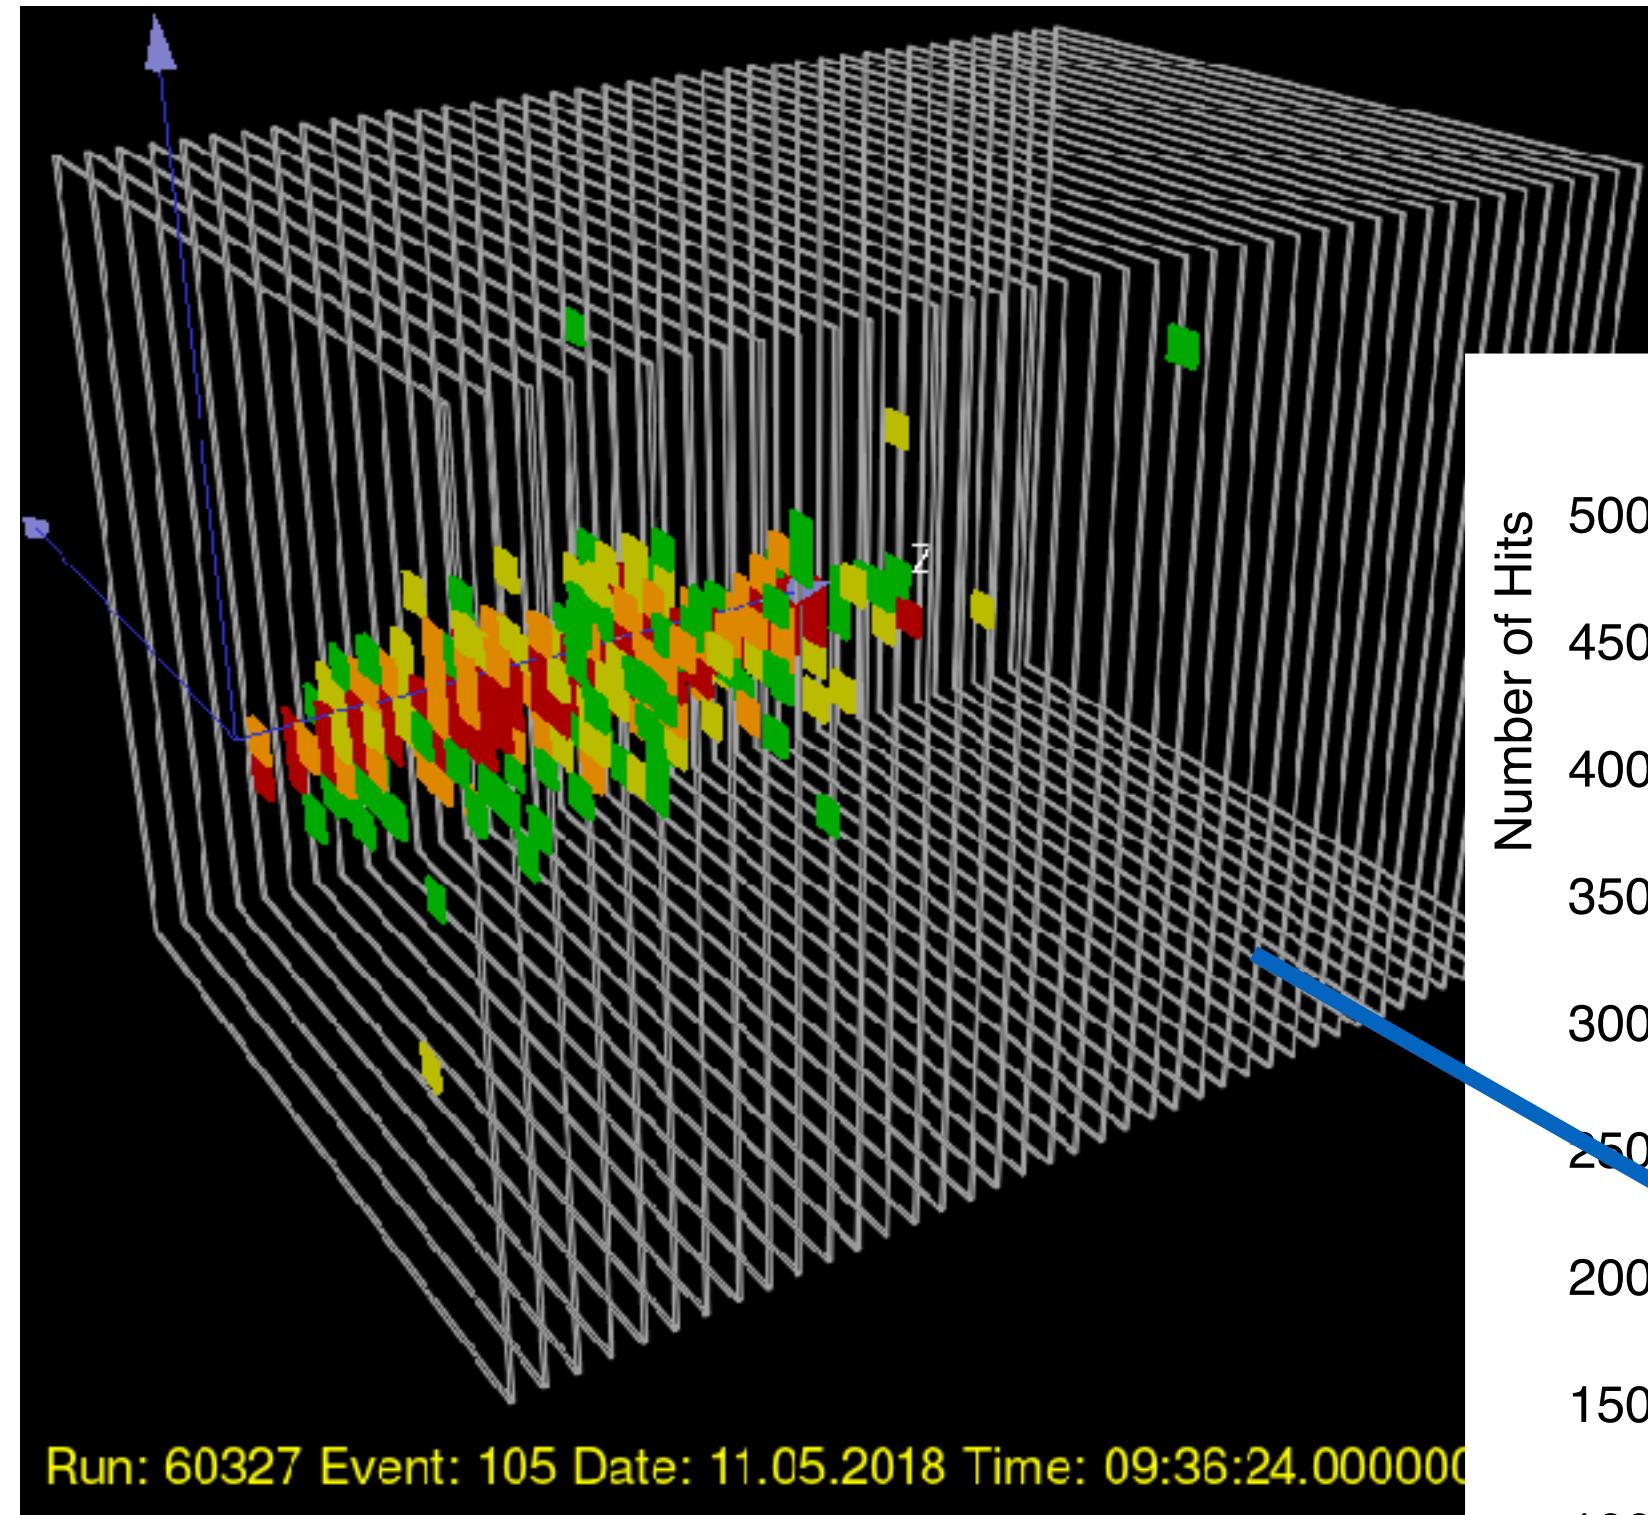

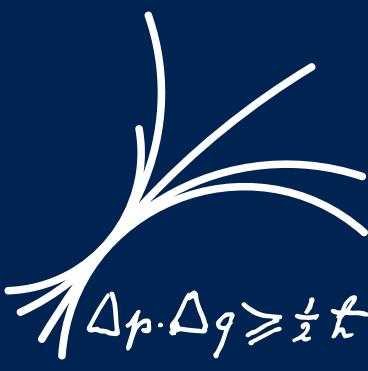

- Hits per event peak at 38 for muons
- ~1% two muon events
- High efficiency, low noise

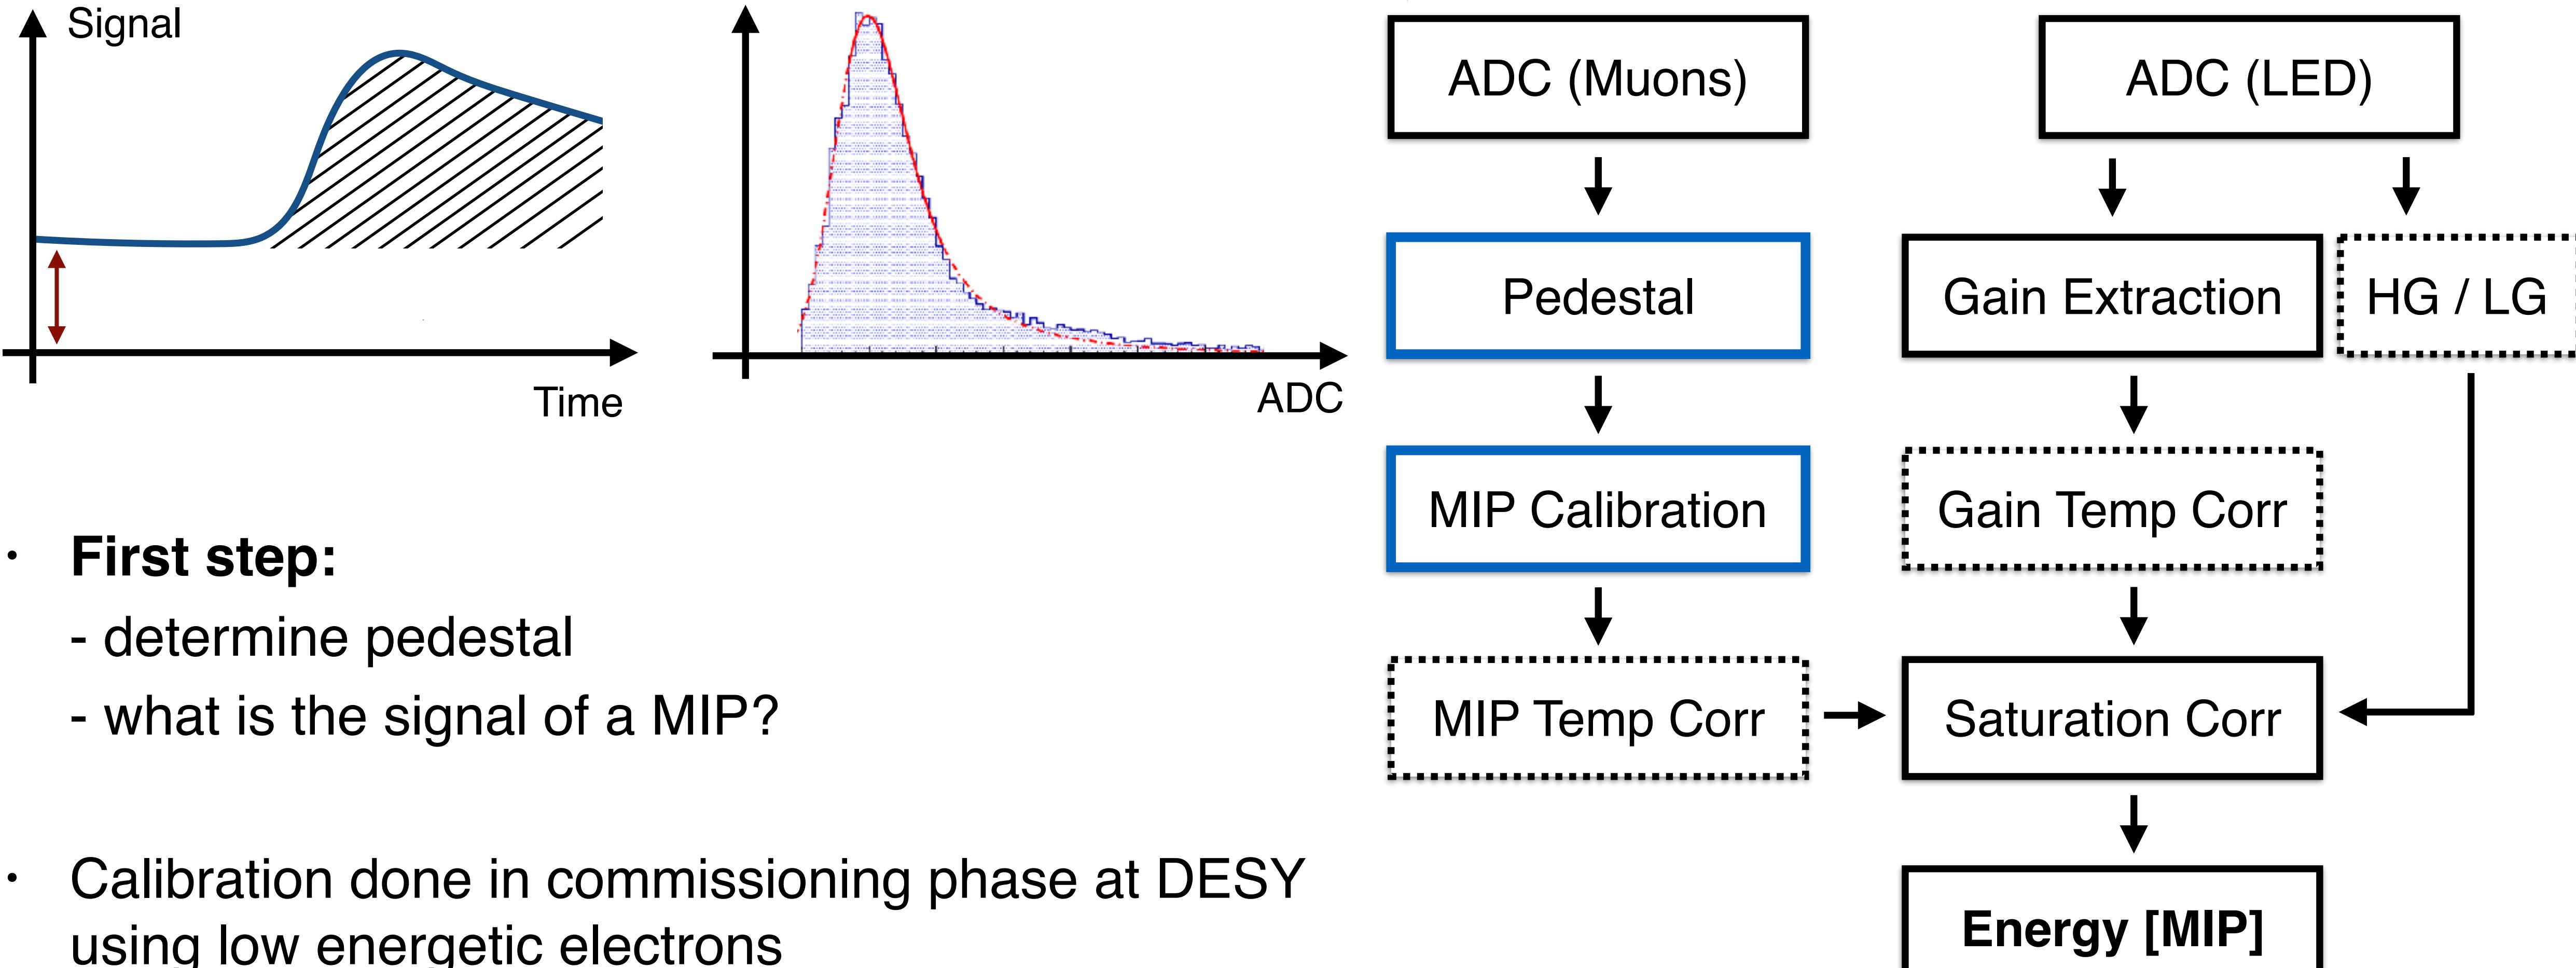

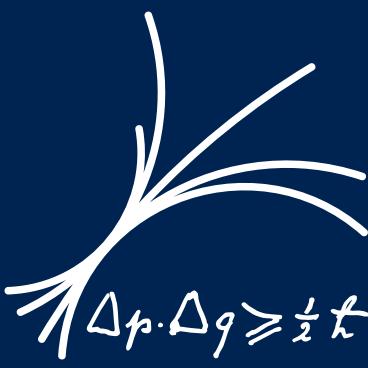

Beam Composition - Electron Beam

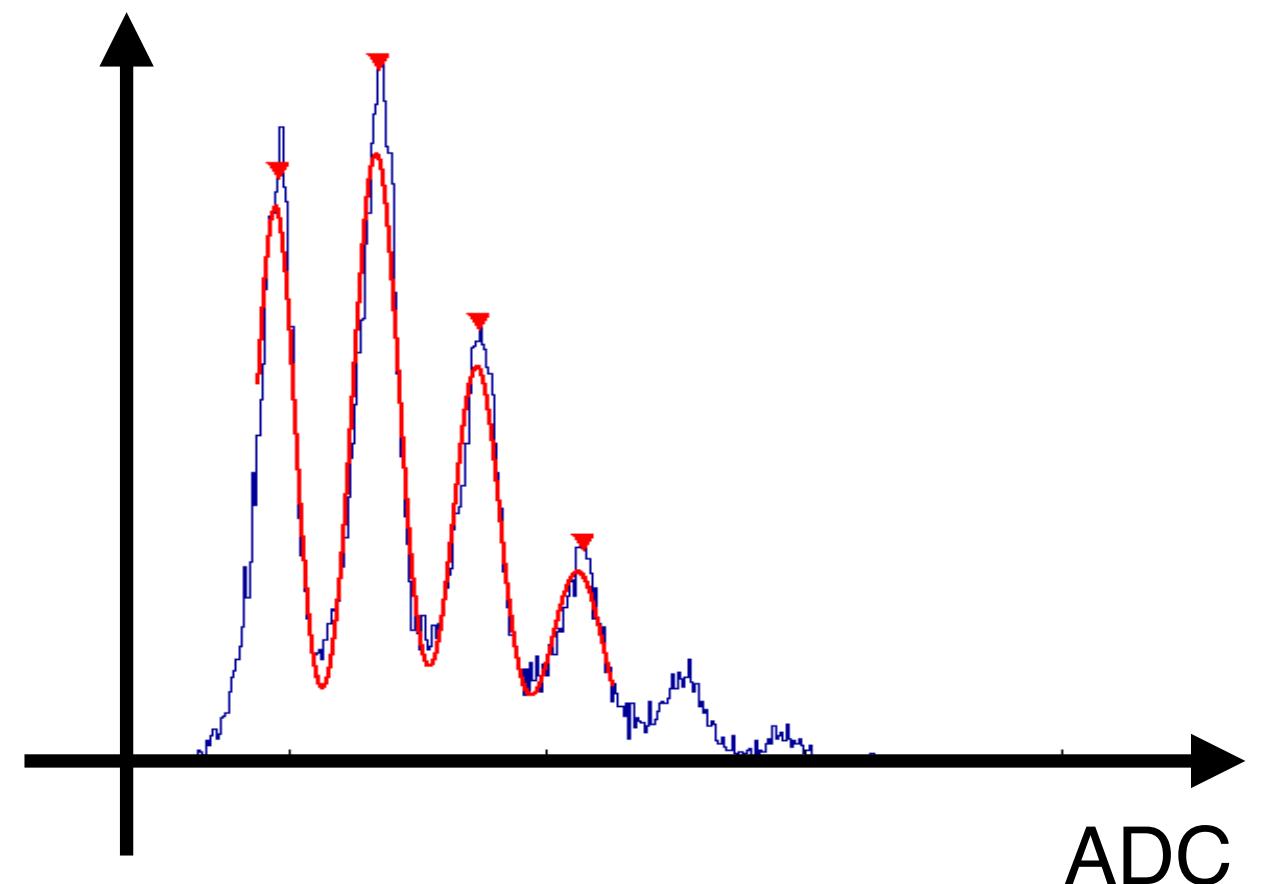

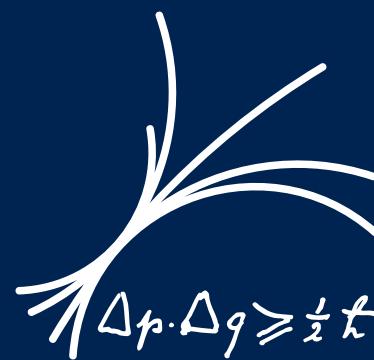

Beam Composition - Electron Beam

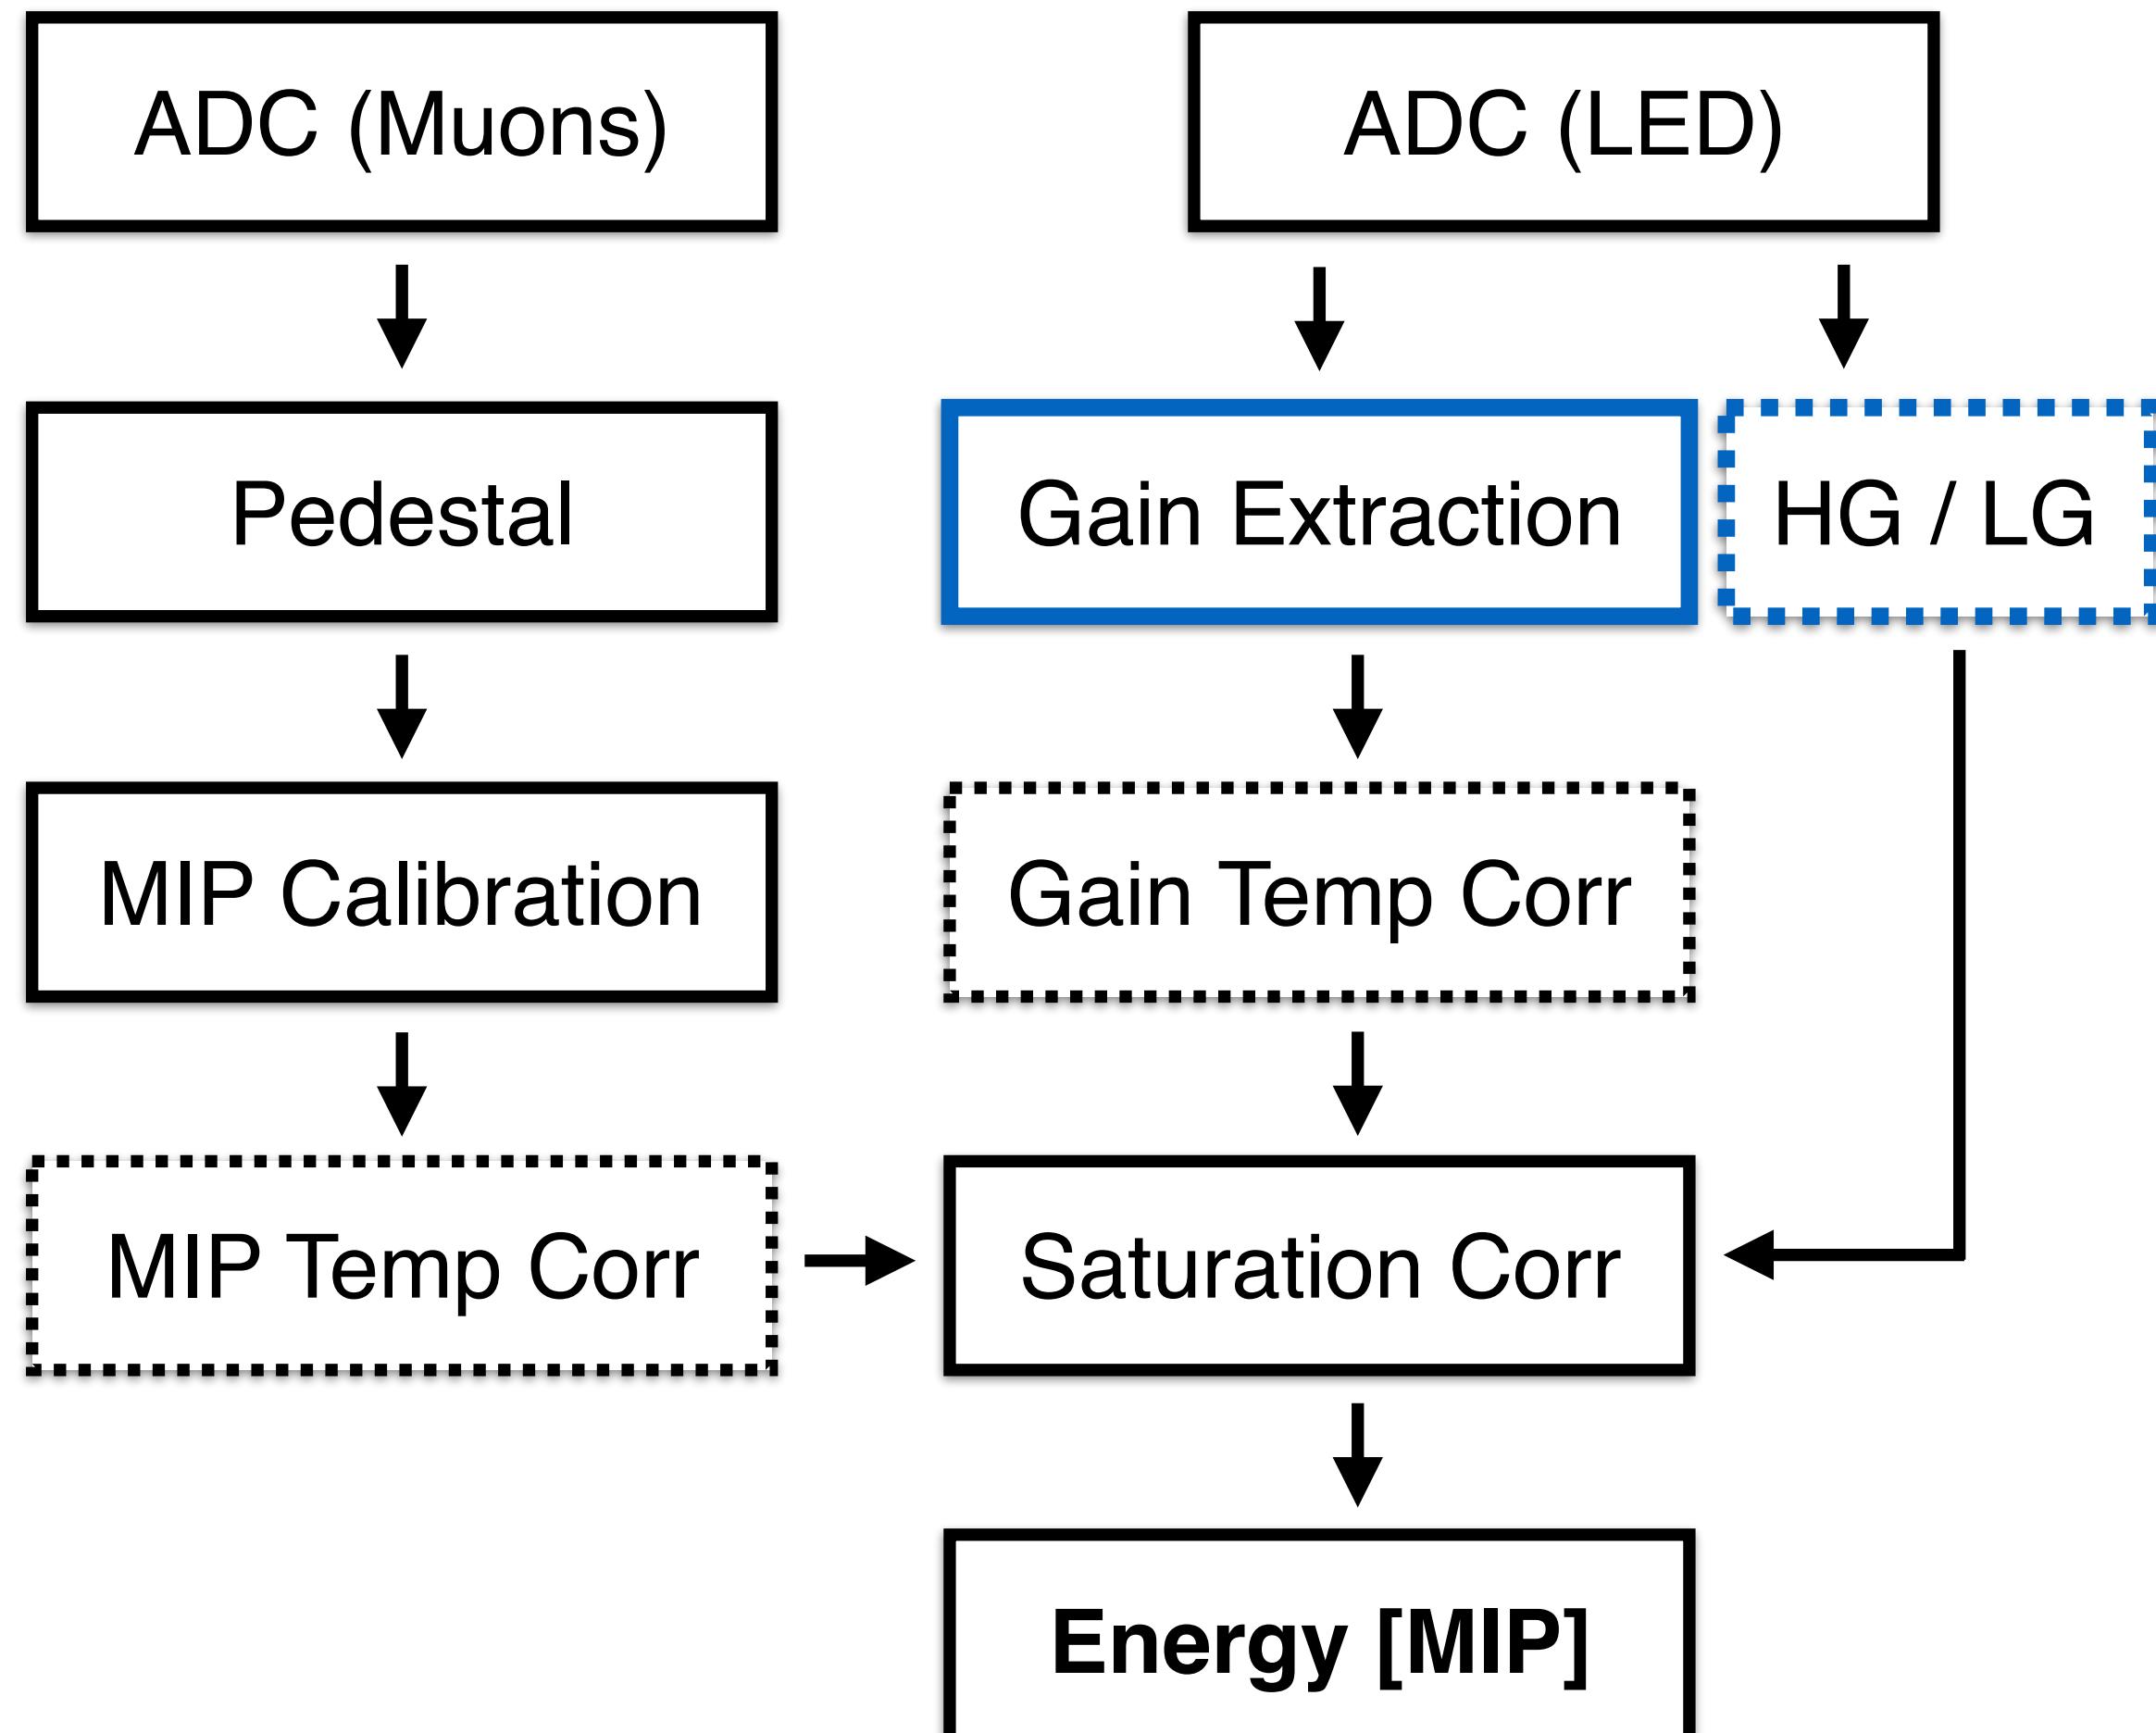

Energy Reconstruction

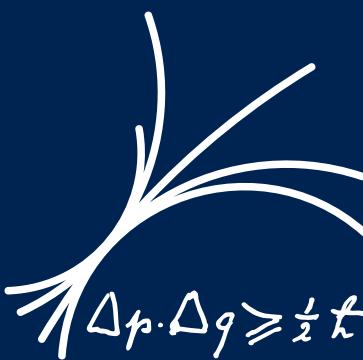

Energy Reconstruction

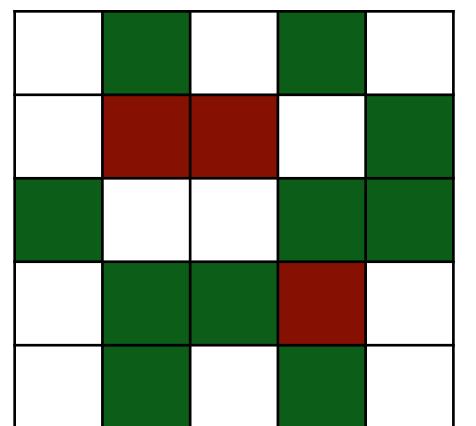

- **Second step:**
 - High gain / low gain inter-calibration
- Two amplification modes to enhance dynamic range while maintaining good low energy resolution
- High gain: calibration done during commissioning
Low gain: currently, approximate values

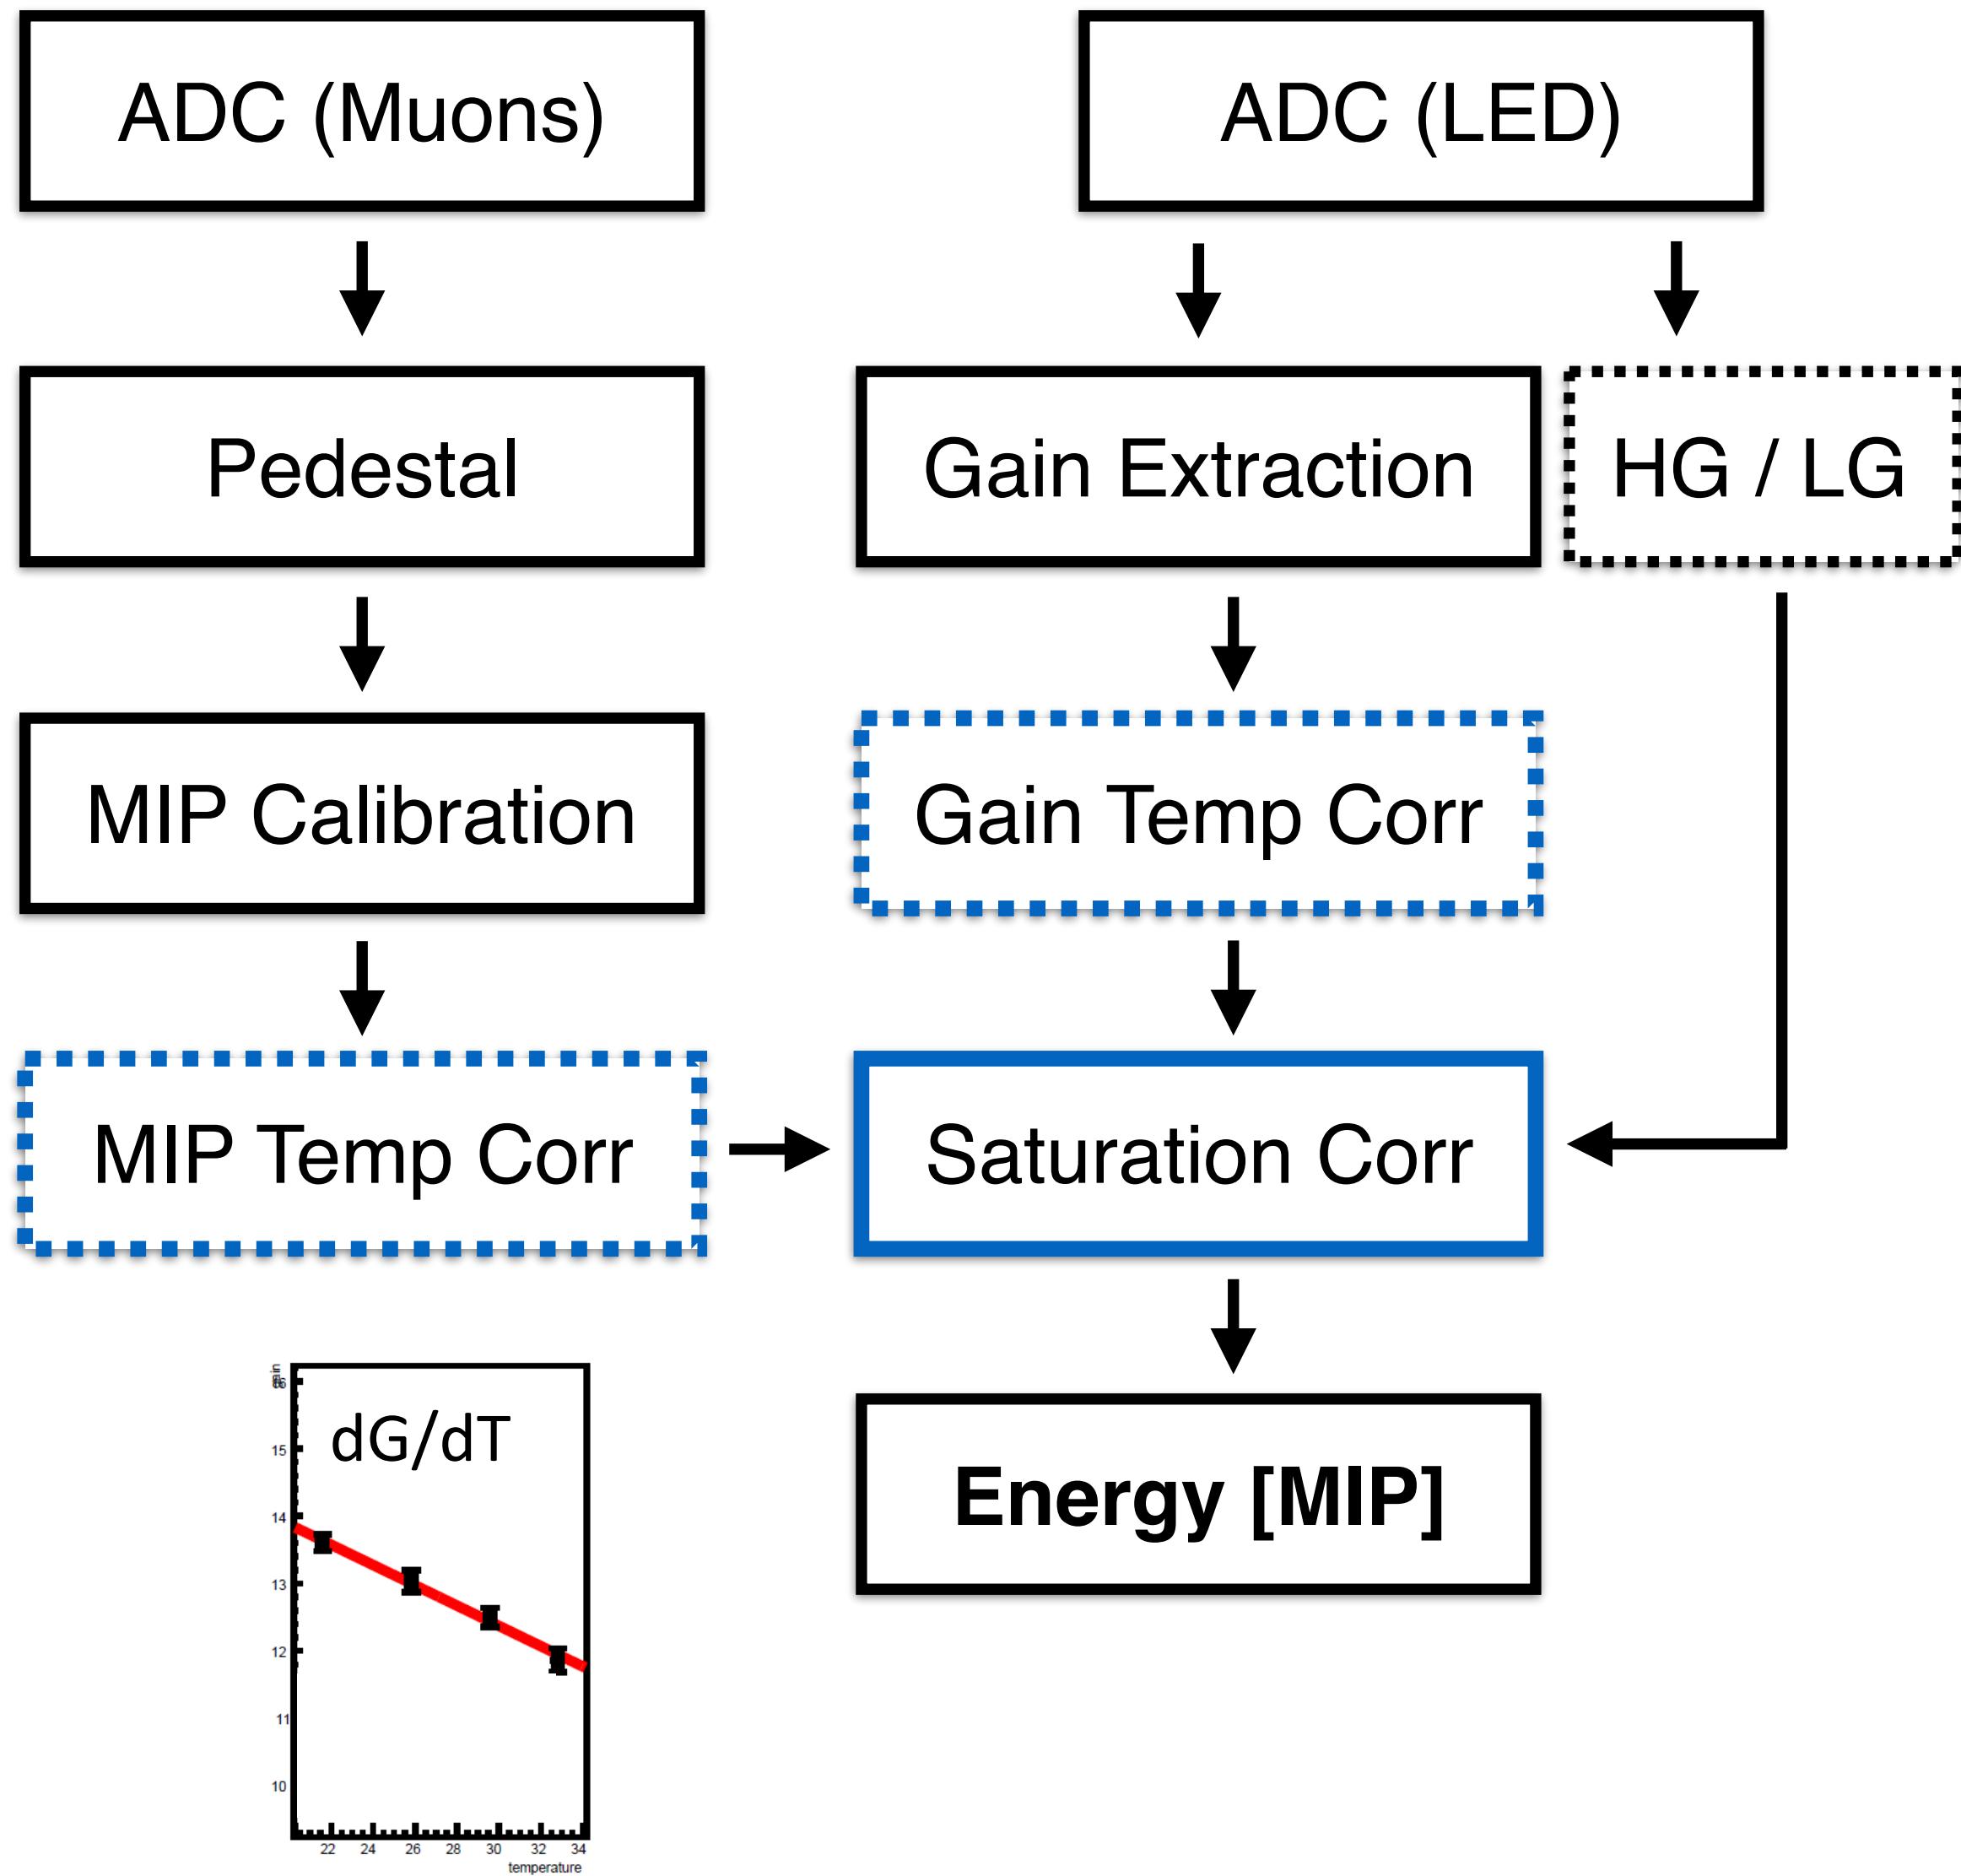

Energy Reconstruction

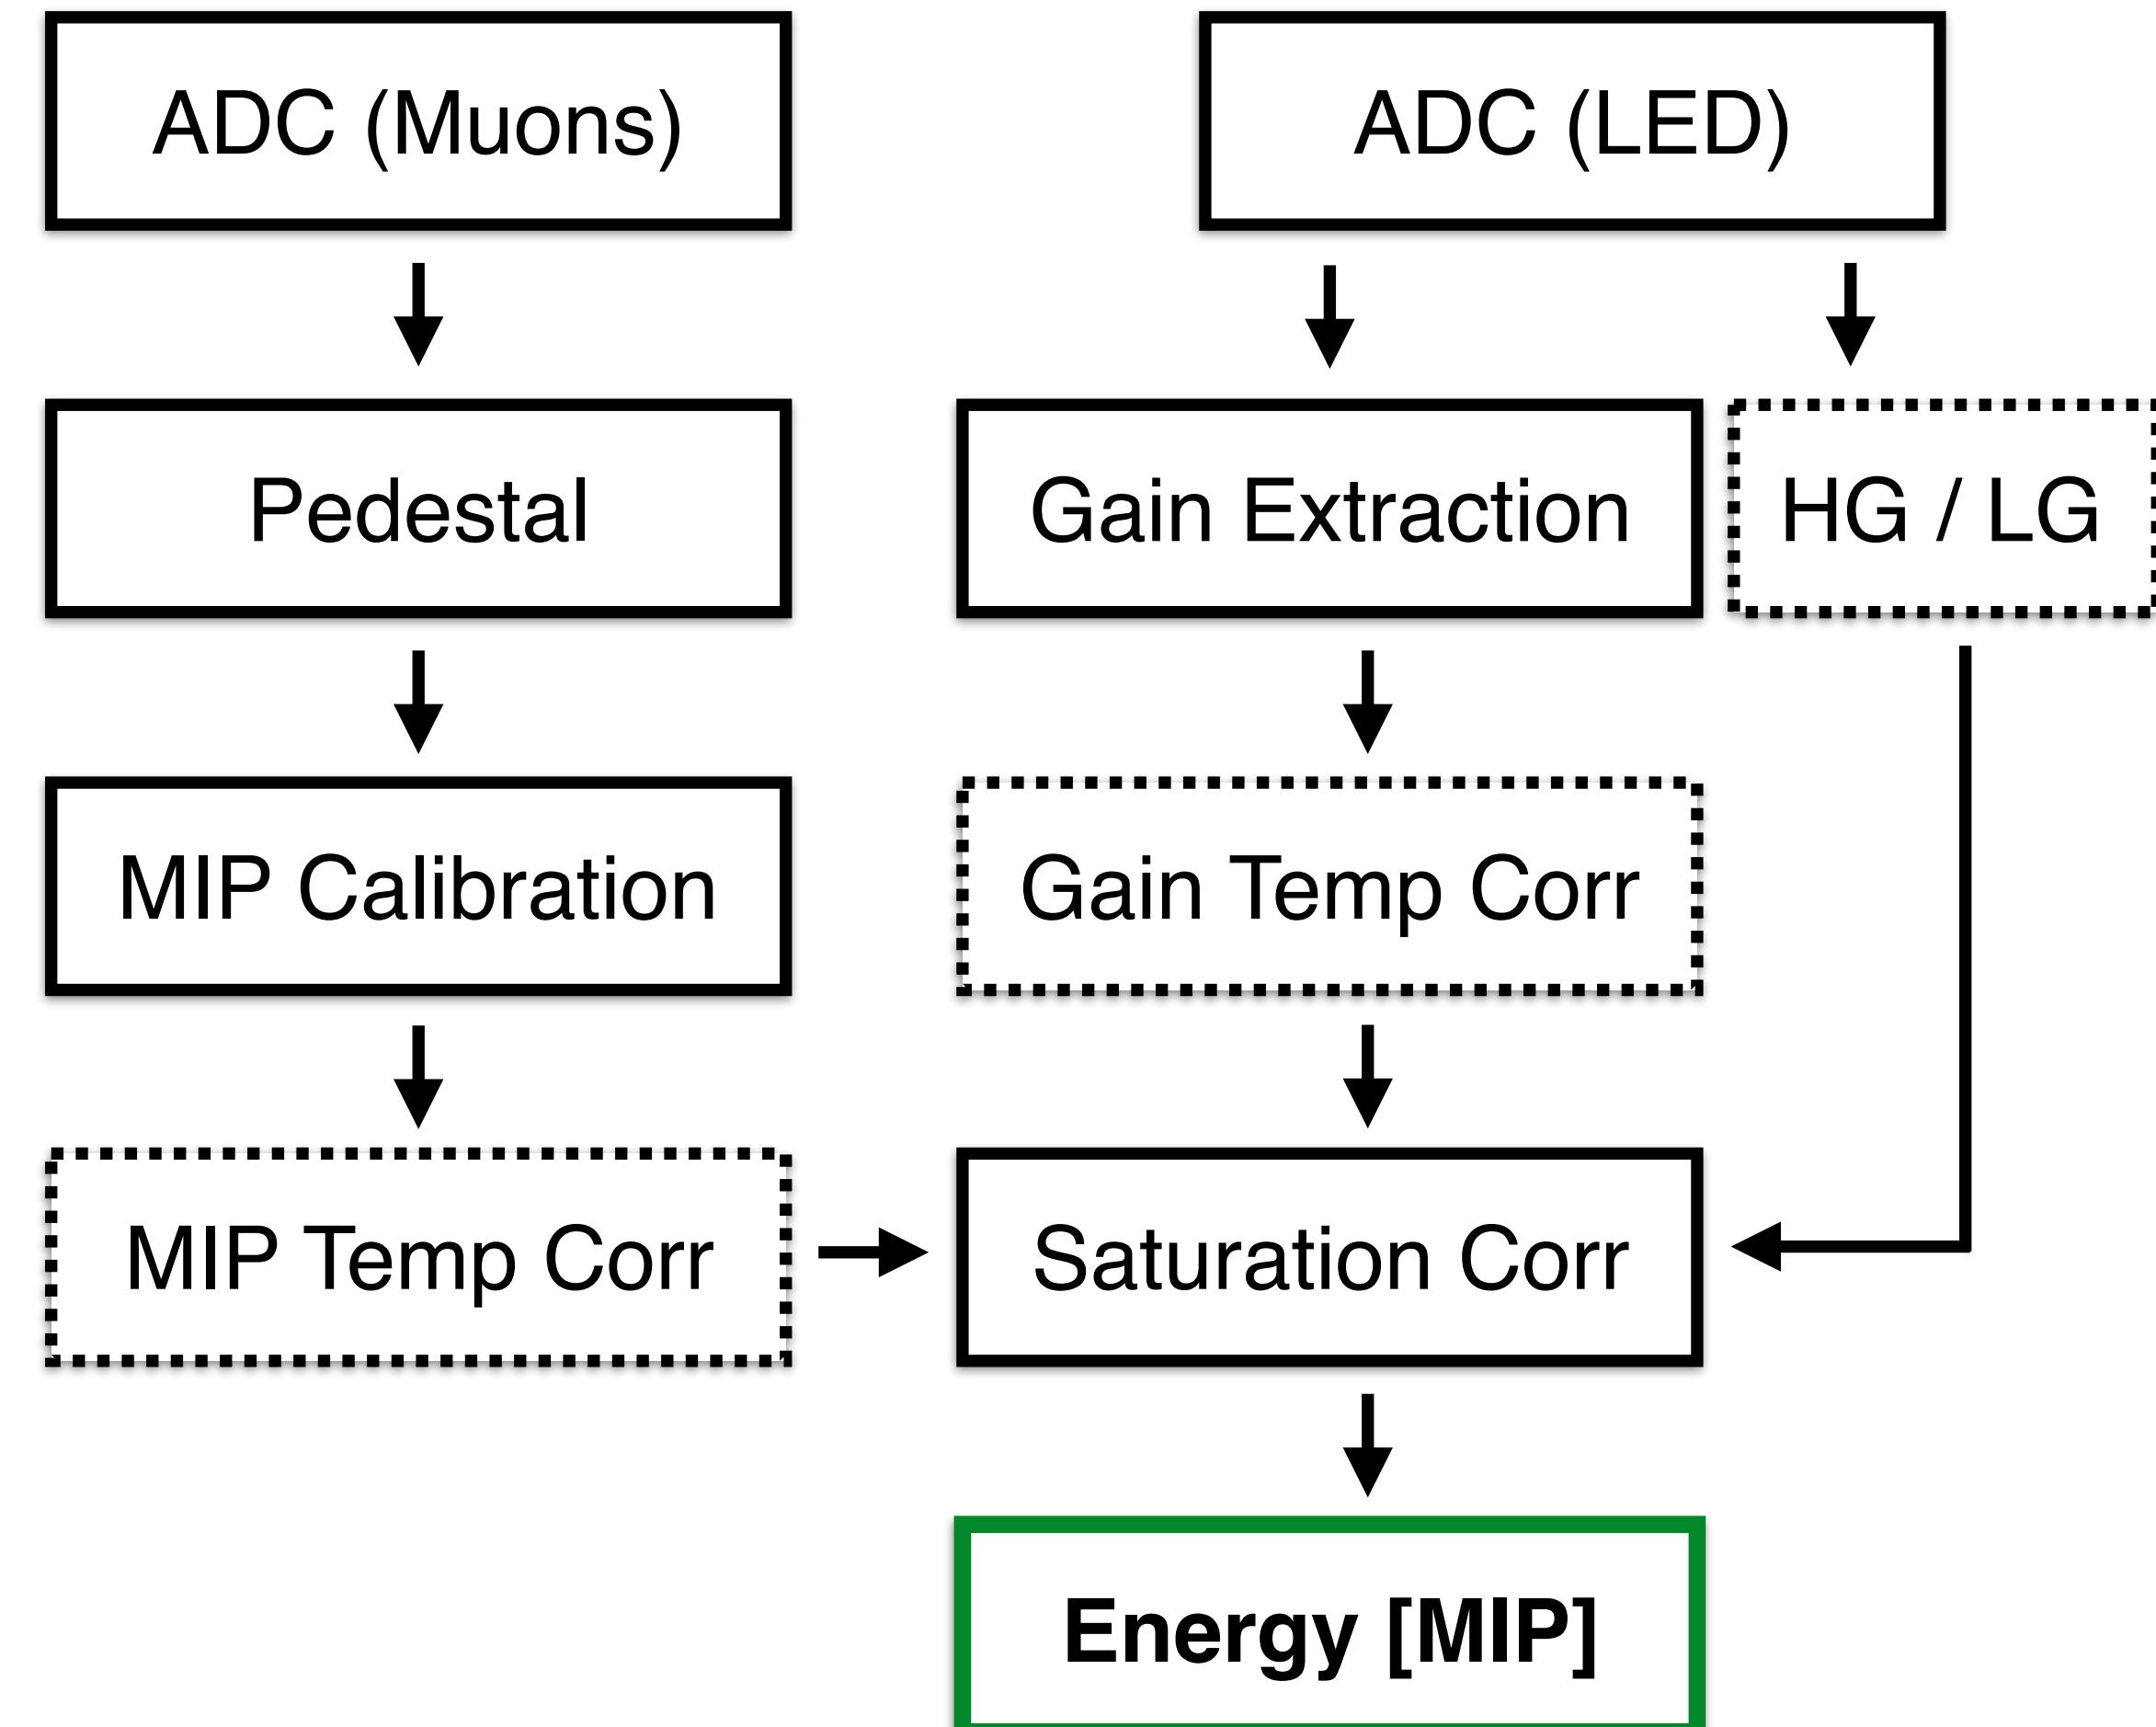

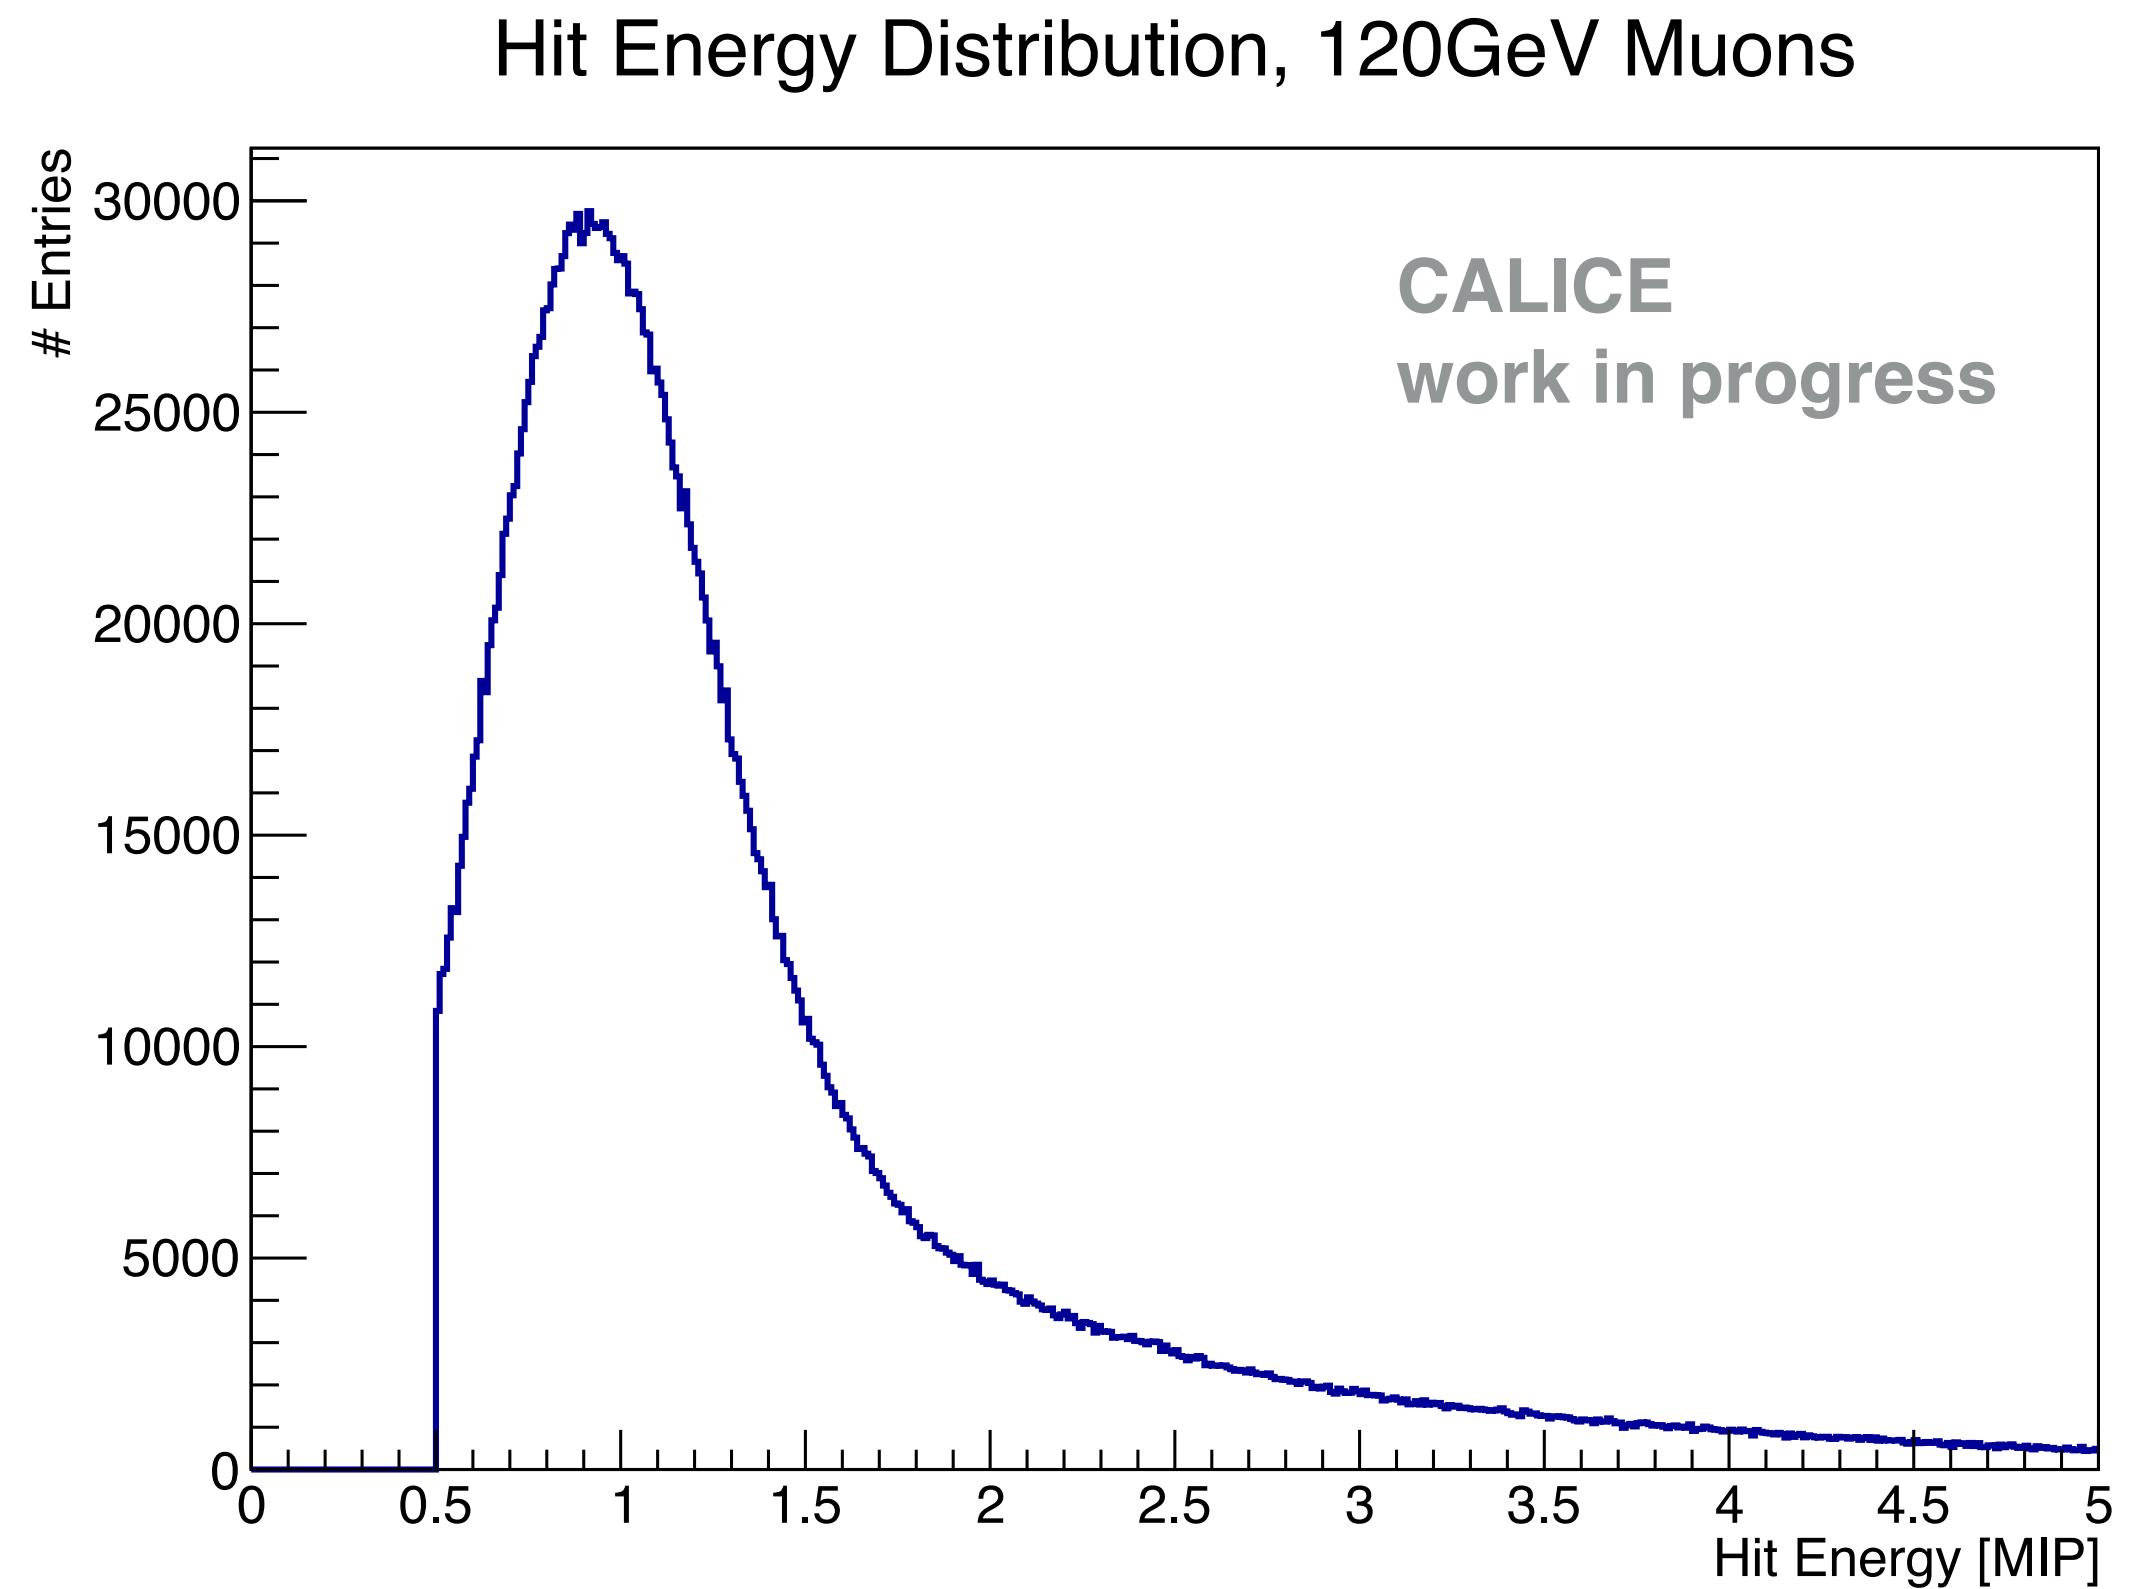

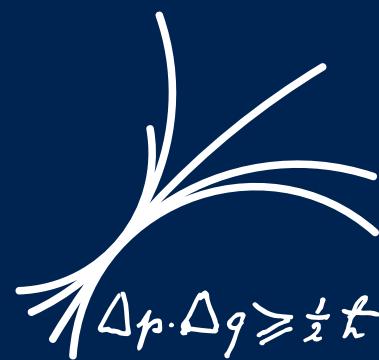

$$f_{\text{saturation}}(N_{\text{fired}}) = N_{\text{total}} \cdot \exp \left[-\frac{N_{\text{fired}}}{N_{\text{total}}} \right]$$

- Further corrections:**
 - Account for SiPM Effects
- Saturation correction: simple exponential model
 - only important for high energy depositions
- Temperature dependence of gain (MIP): not yet used
 - *temperature compensation*:
adjust SiPM voltage with temperature change
 - > only residual corrections needed (if at all)

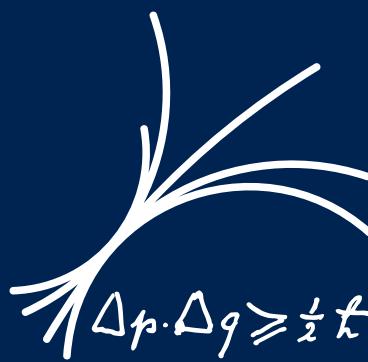

Energy Reconstruction

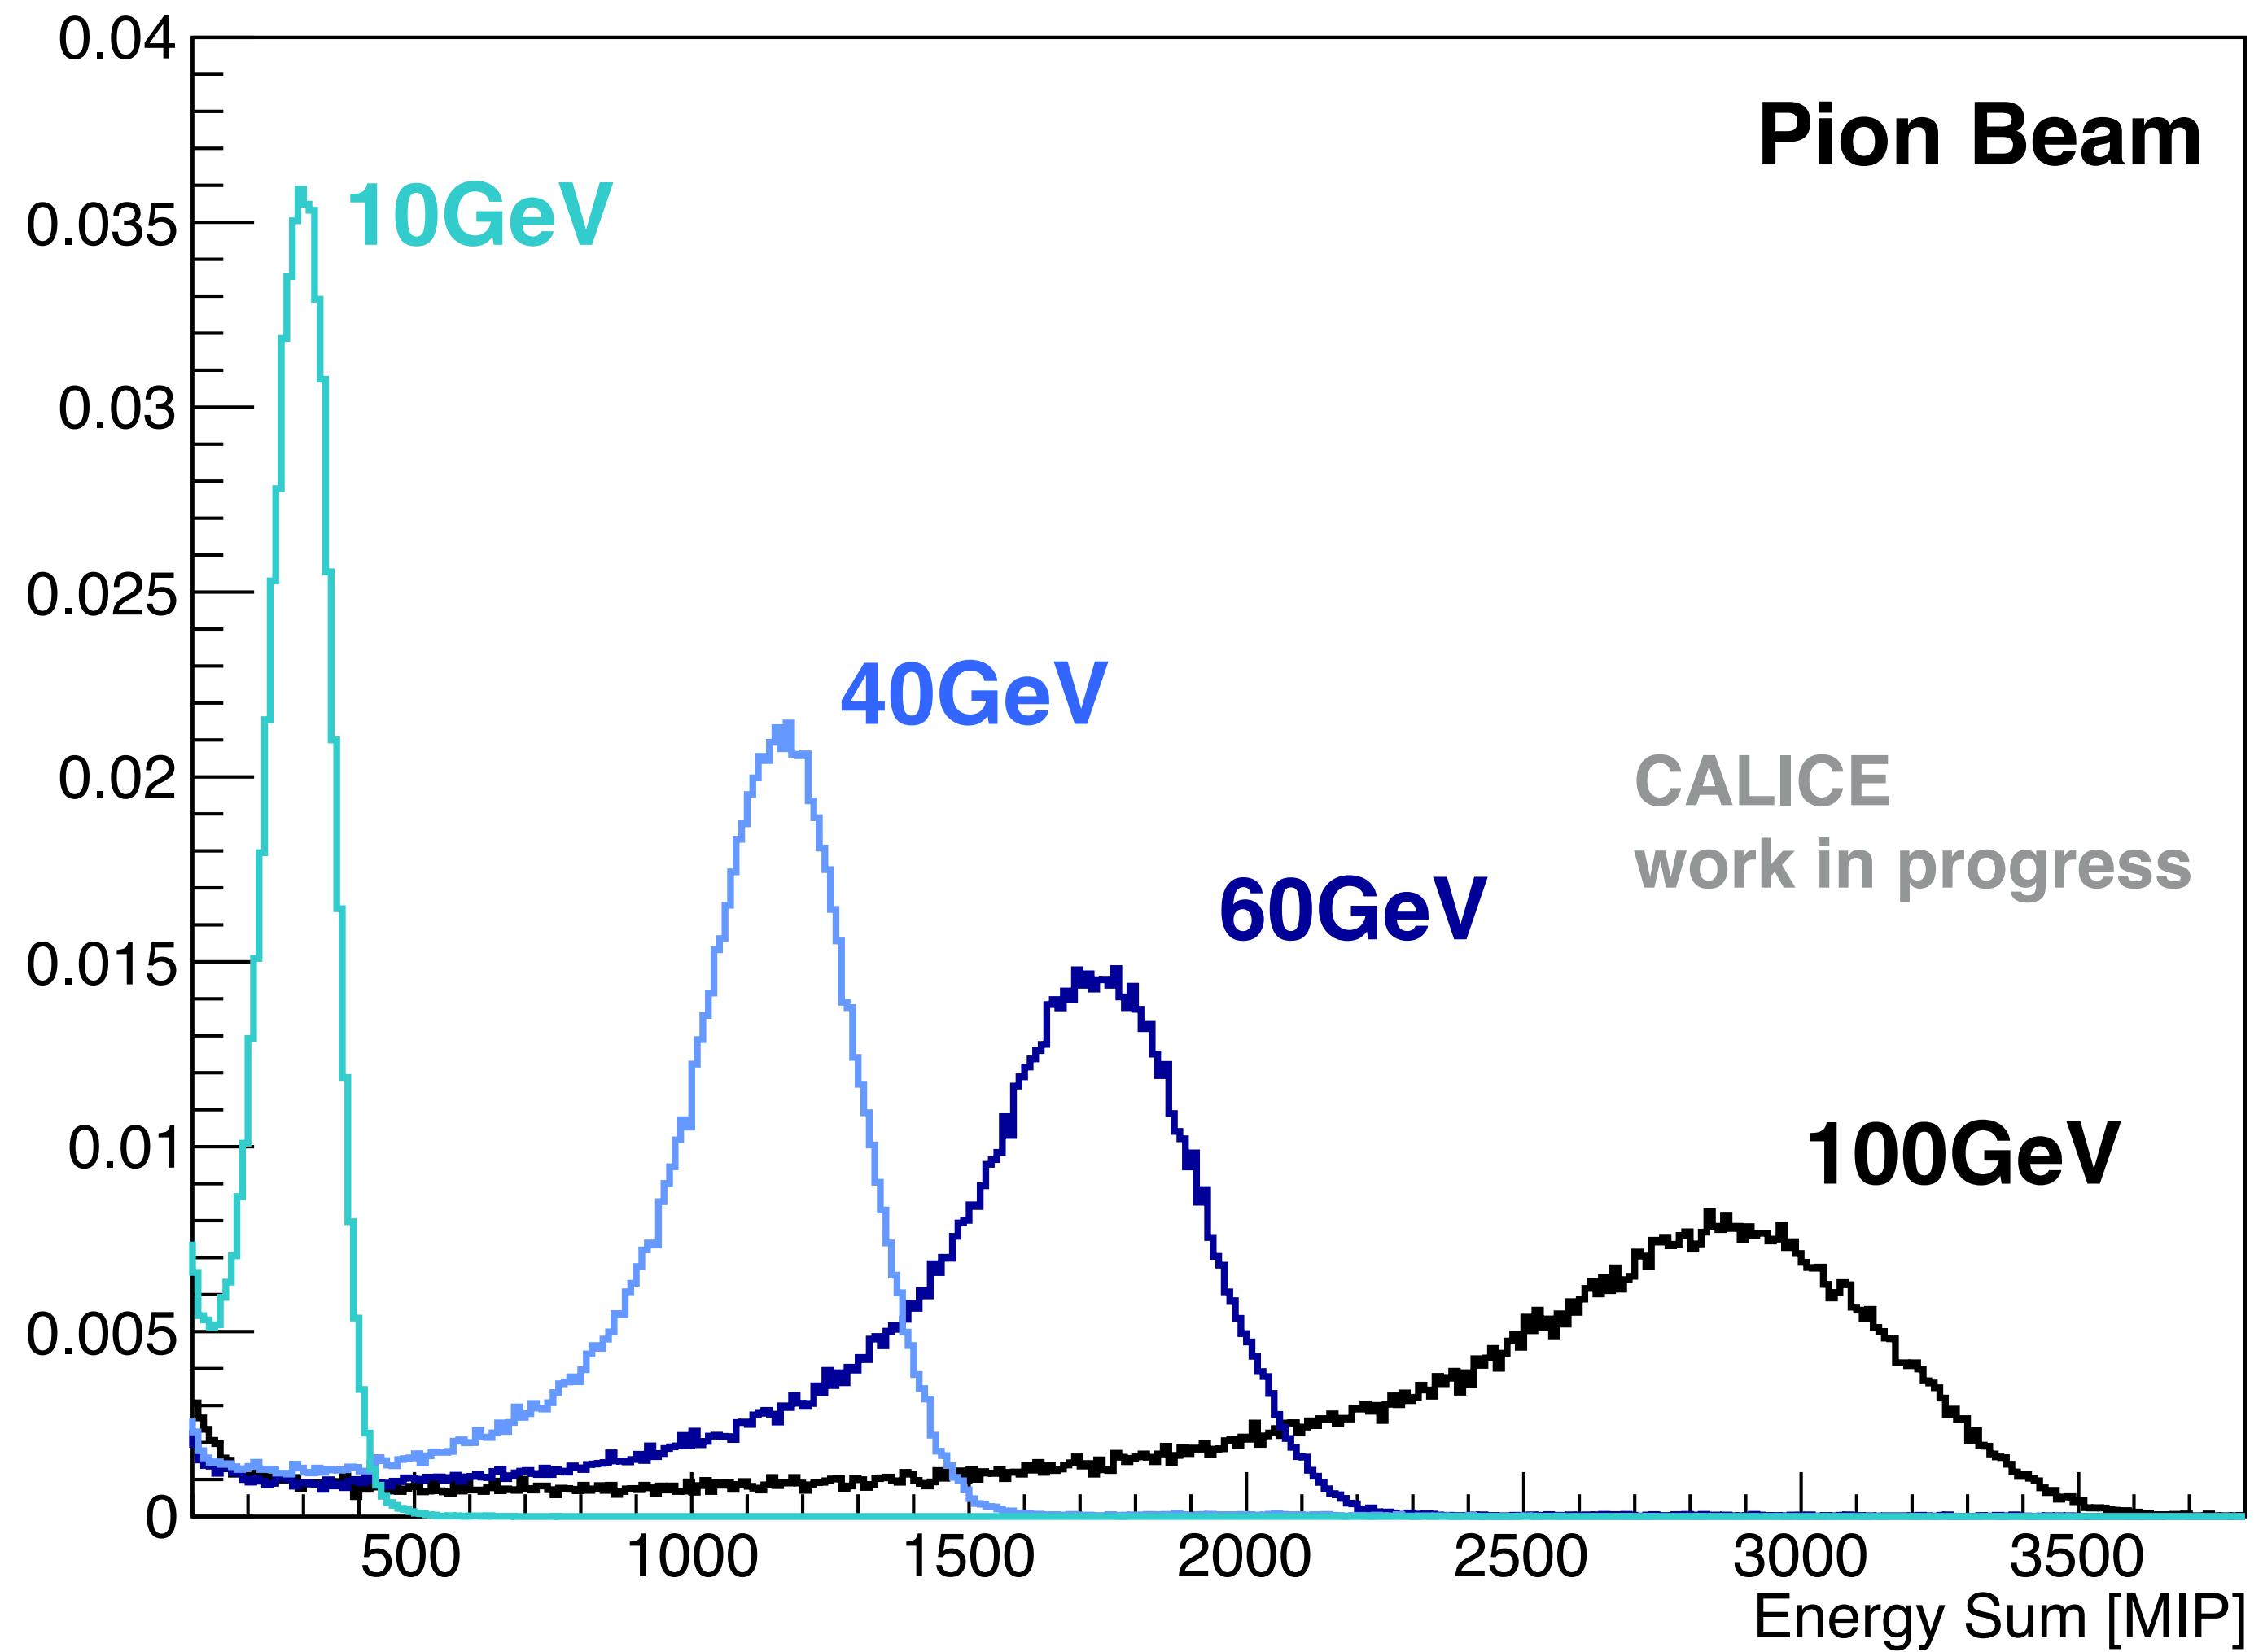

$$E_{\text{calibrated}} = \frac{A}{A_{\text{MIP}}} * f_{\text{saturation}} \left(\frac{A}{A_{\text{pixel}}} \right)$$

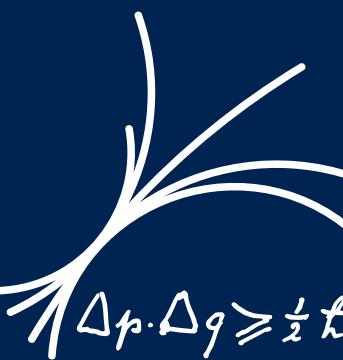

Hadron Beams

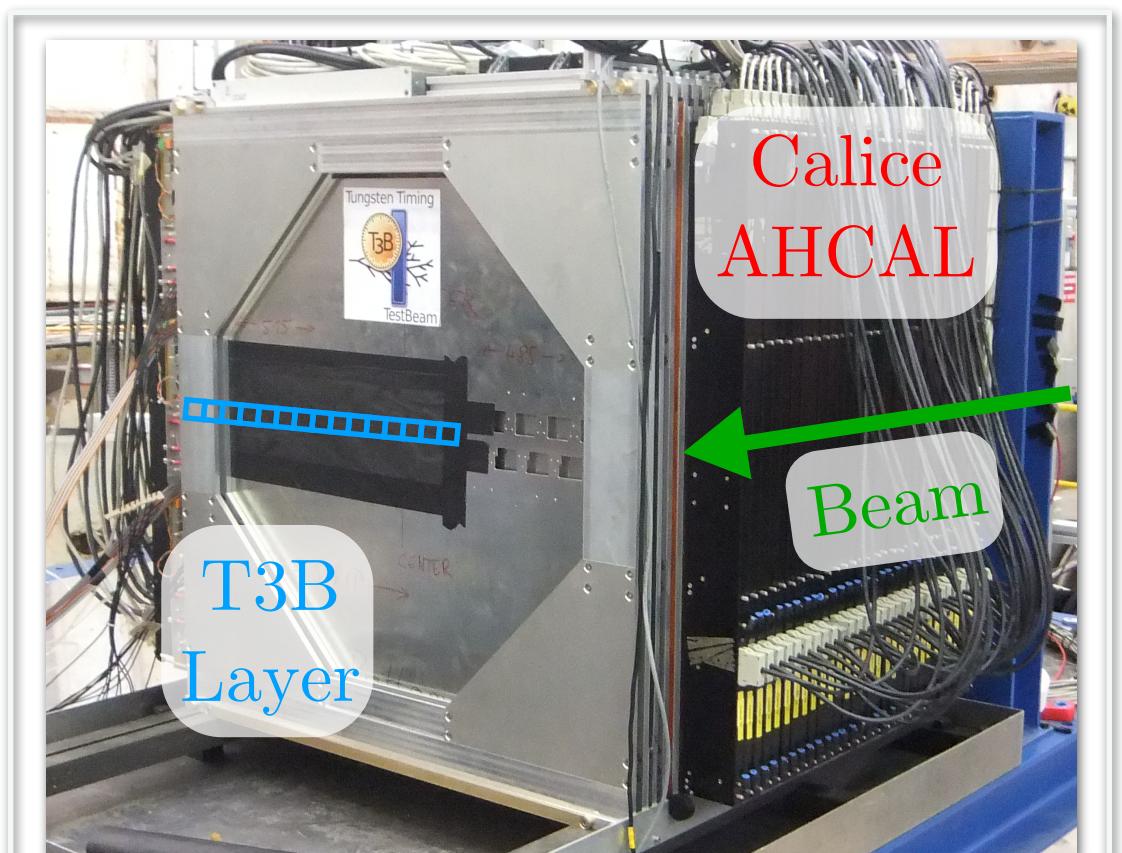

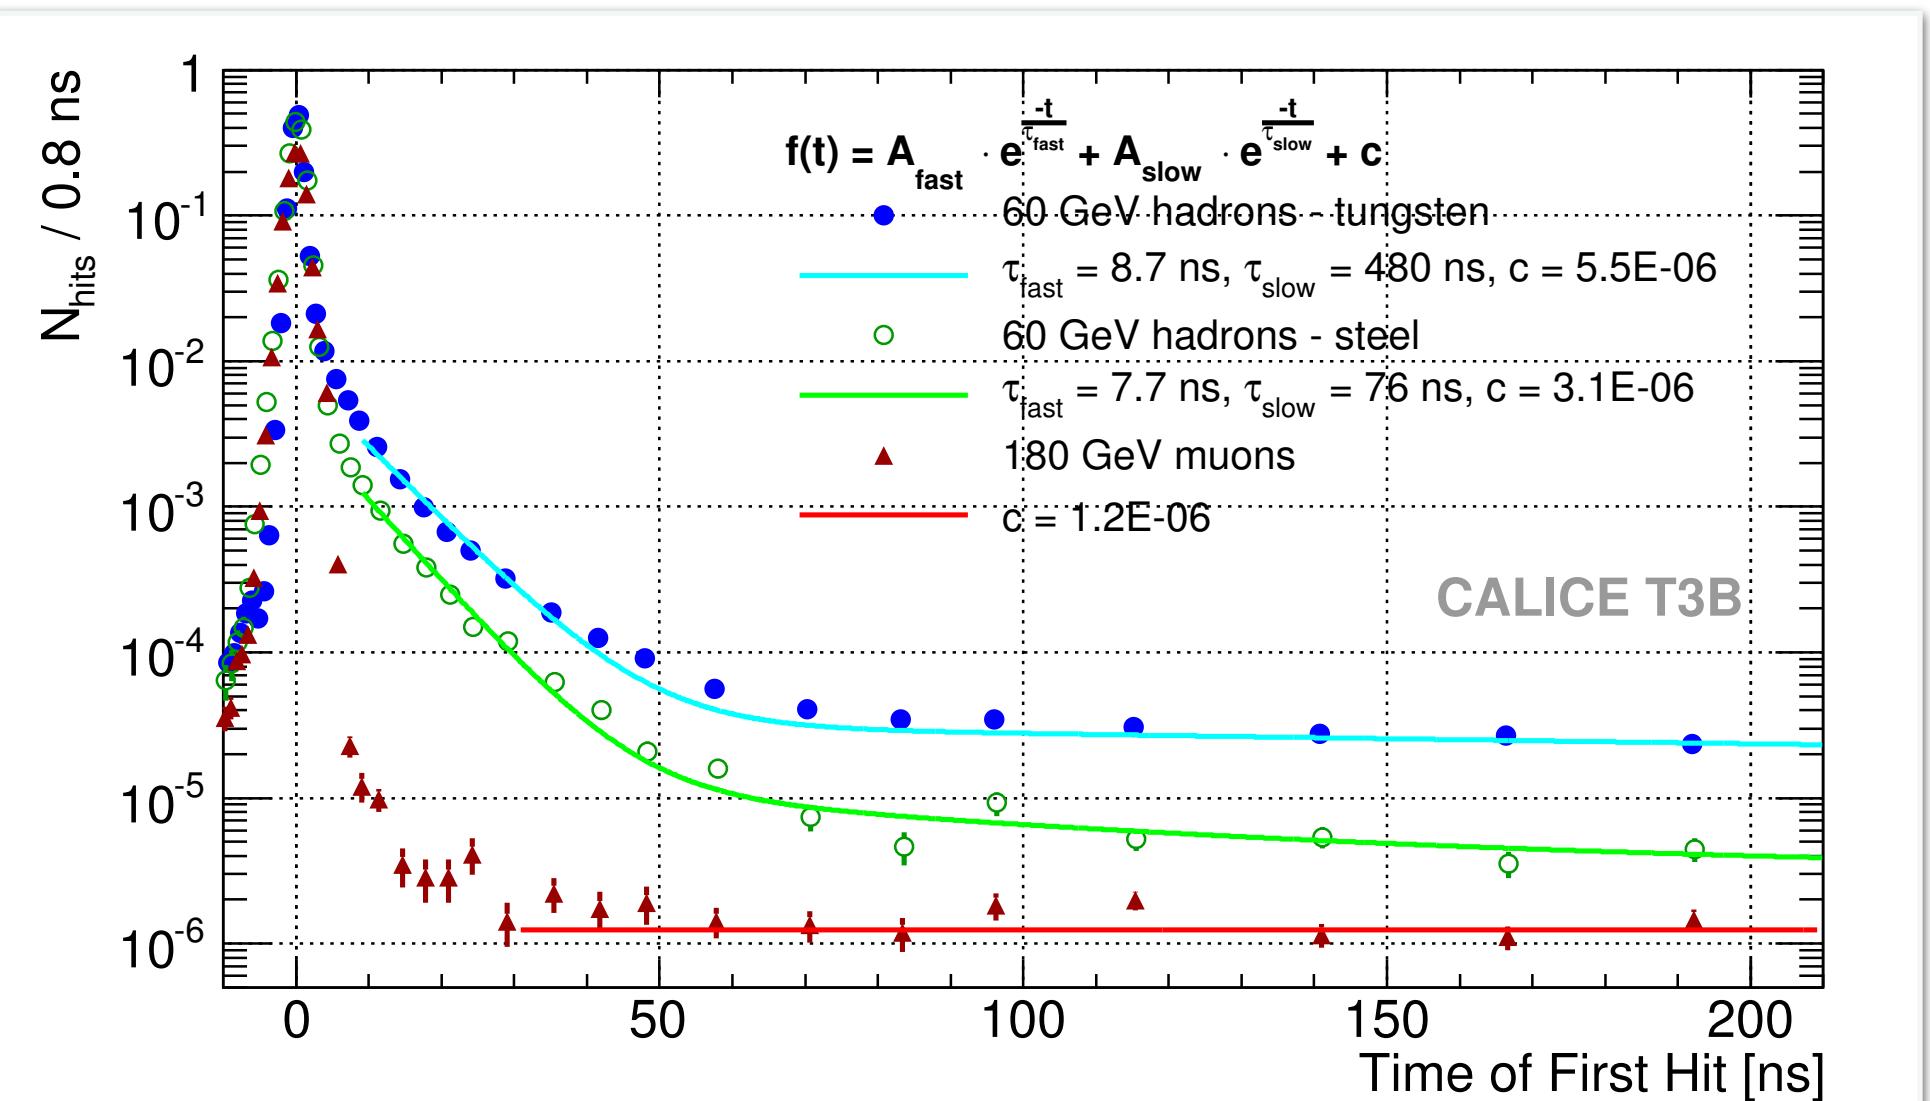

- Preliminary energy reconstruction
- Only basic muon rejection

Timing

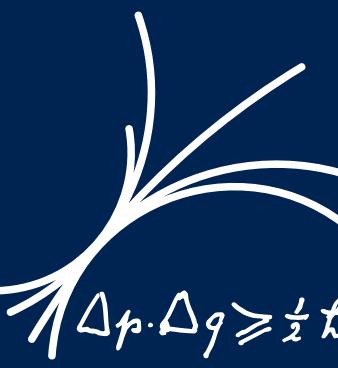

- Complex time structure of hadronic showers:
Slow neutrons from hadronic processes produce late energy depositions
- Previous measurements:
T3B parasitic to physics prototype
- Now: Timing capabilities in whole prototype
- Readout ASIC (SPIROC 2E) has two timing modes:
 - test beam mode: ~1.2ns / TDC
 - ILC mode (80ps / TDC) possible

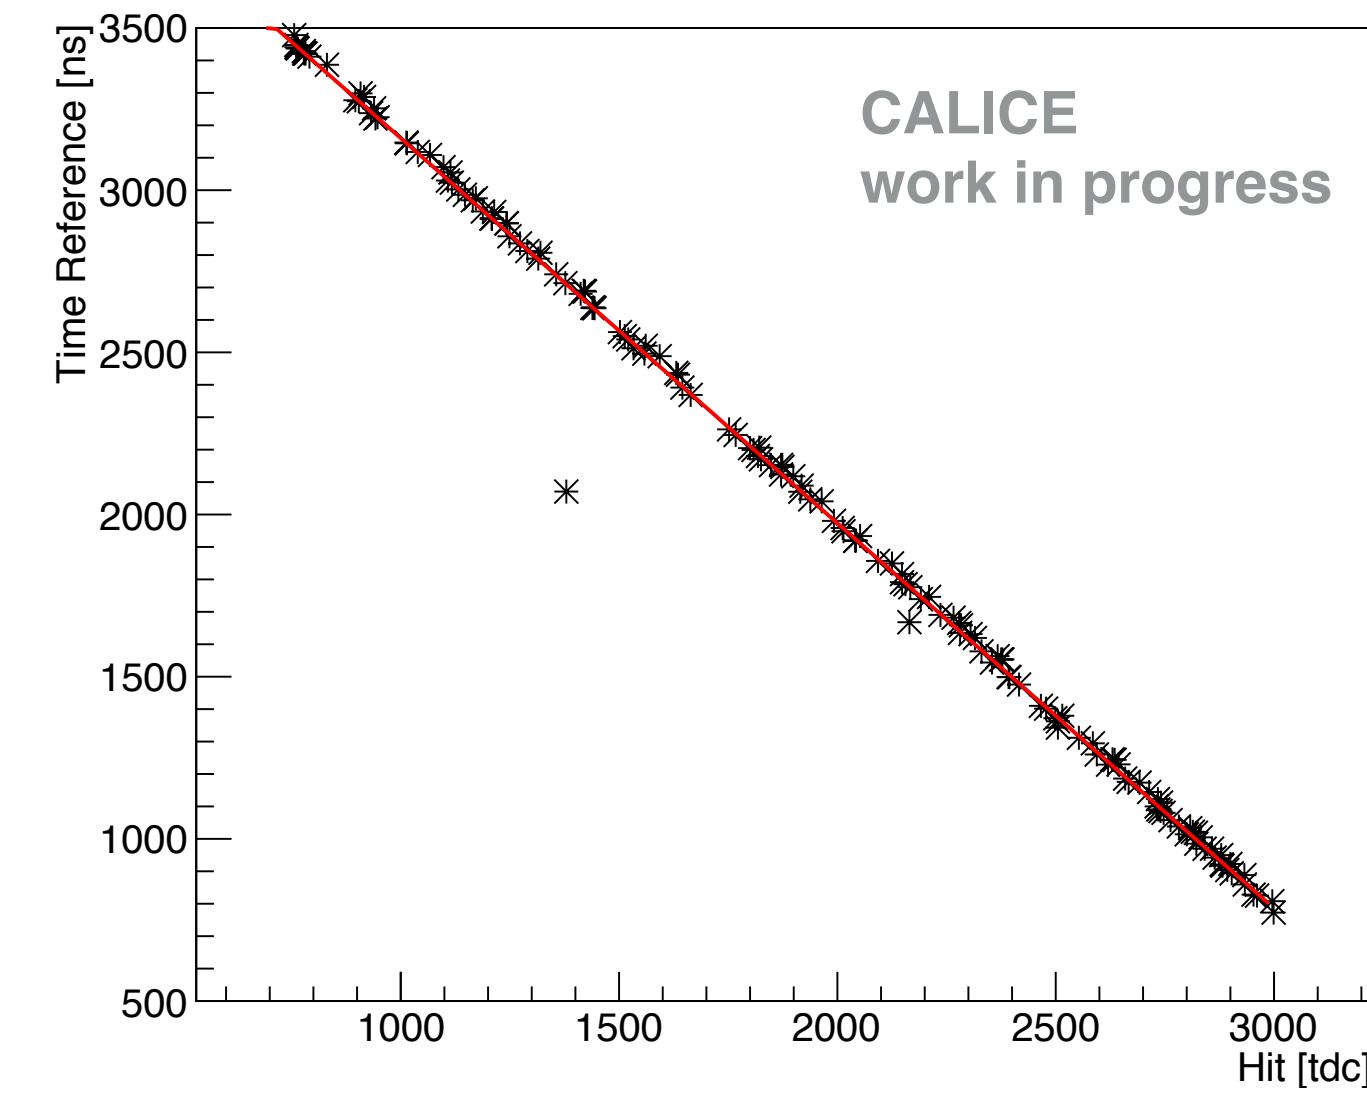

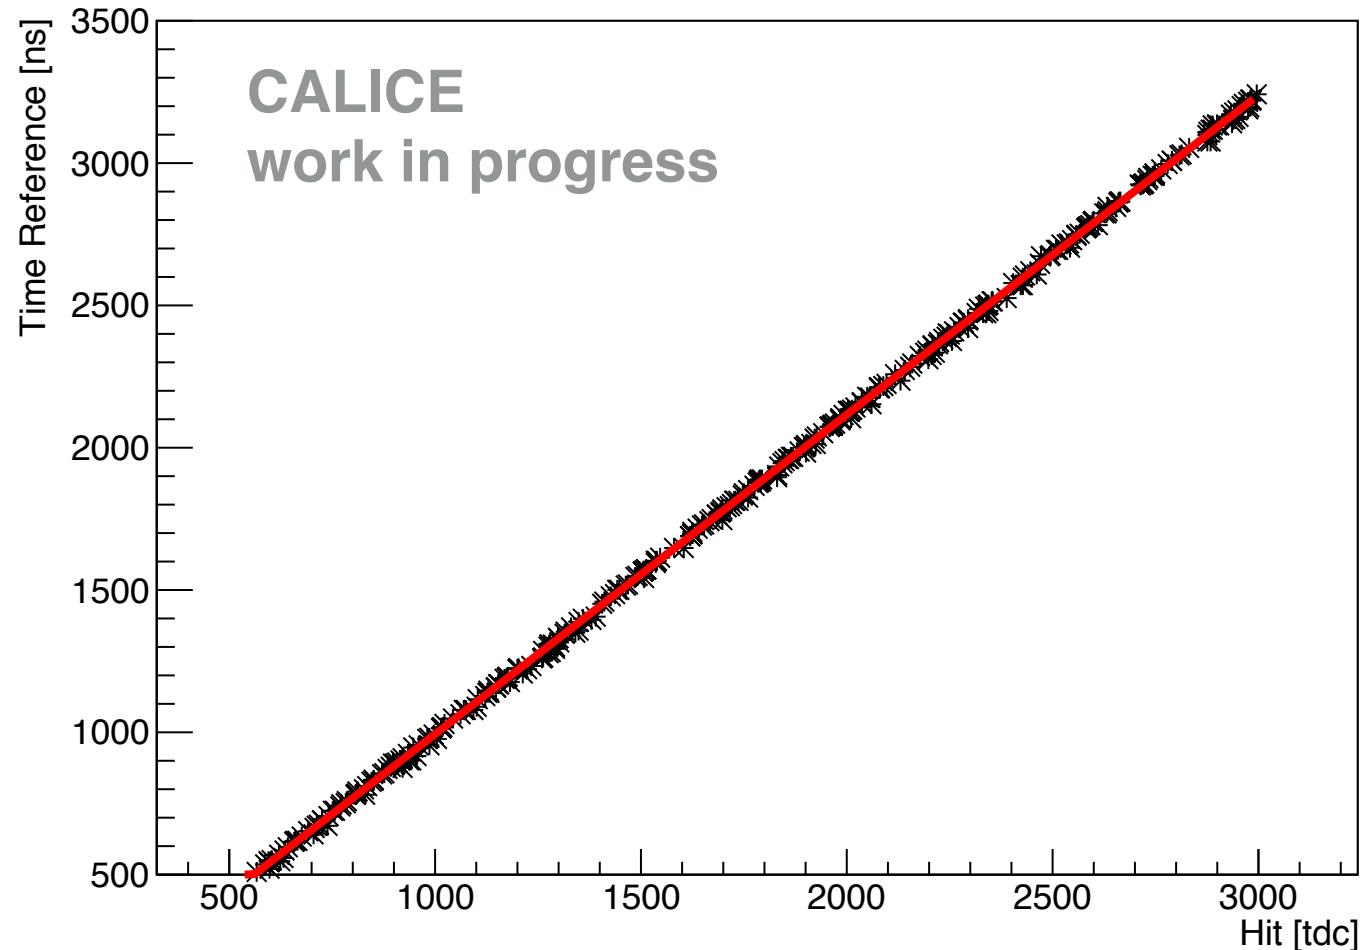

T3B behind physics prototype

Time Calibration

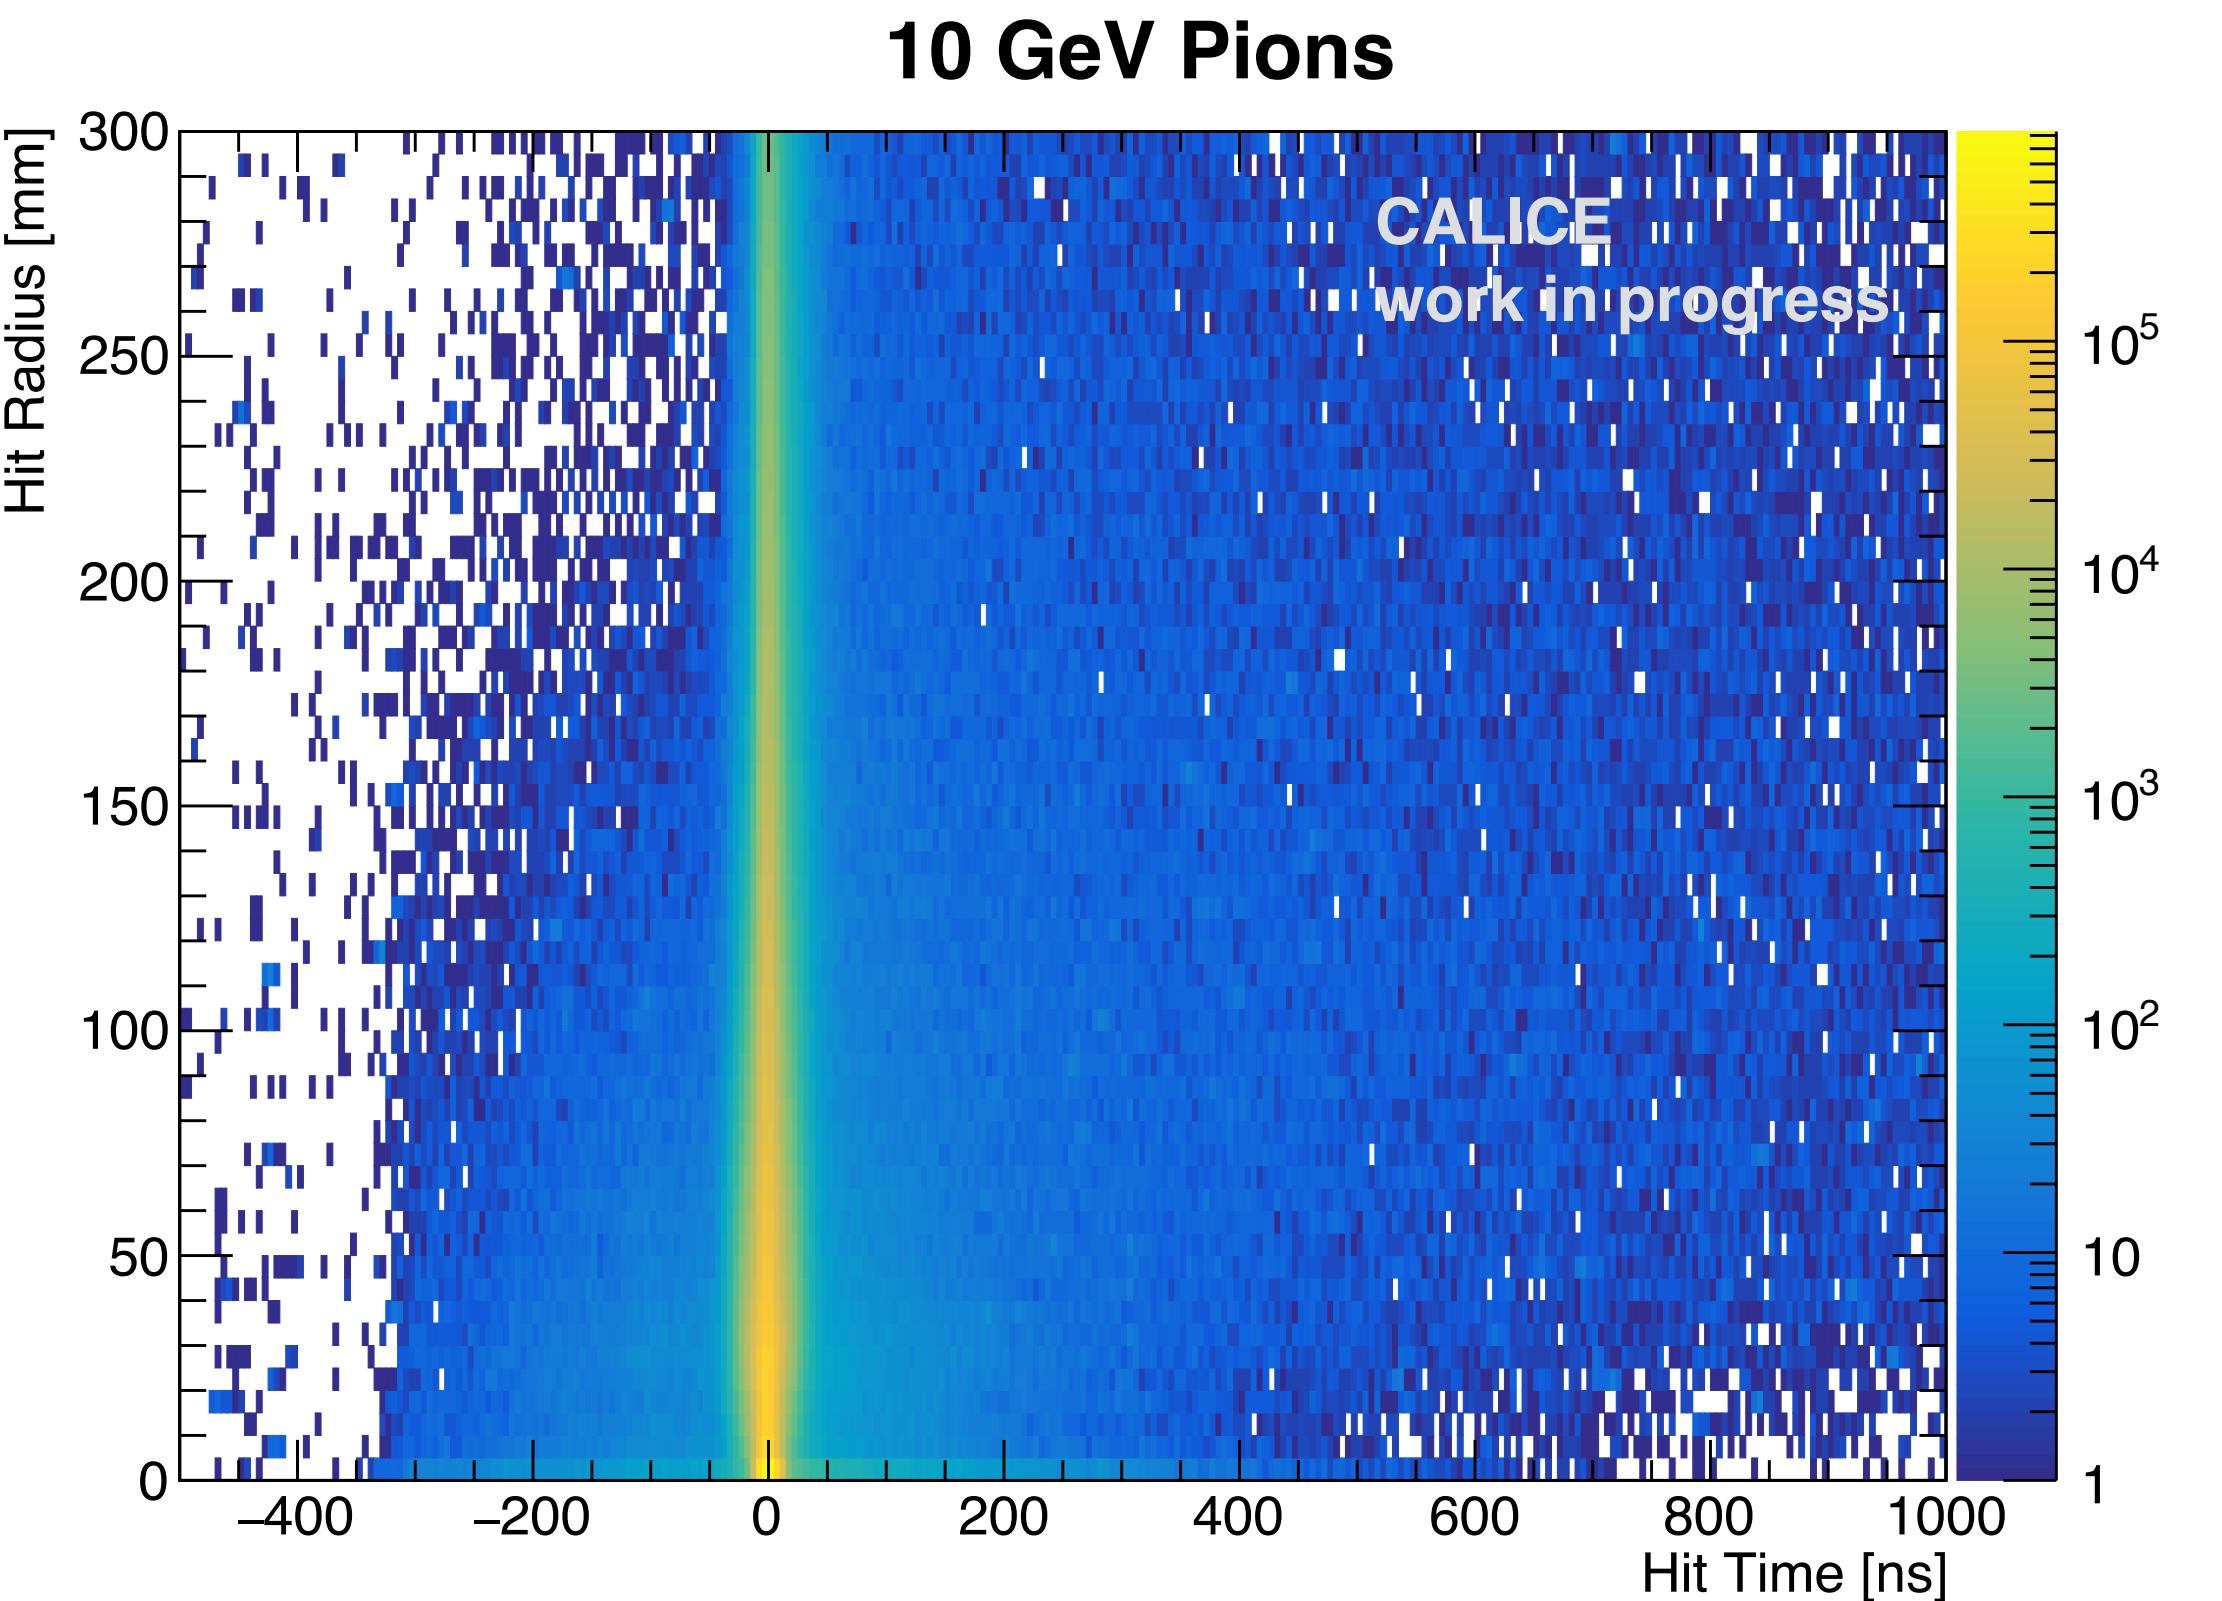

- Muon scan used for calibration
- Trigger scintillator for time reference is managed by beam interface board (BIF)
- Time calibration procedure established
- Two slopes per chip, fit with per mille precision needed
- Offset for each memory cell (16 per channel) 700'000 calibration constants
- Corrections missing:
 - time walk
 - non-linearity

Time Reconstruction

- Preliminary time reconstruction:
 - time calibration not complete
 - corrections missing
- Readout ASIC shows problems for high rates
 - hopefully recoverable; analysis ongoing
- Late energy depositions visible
- Outlook: investigate complex time structure of hadronic showers

Summary

- Successful test beam campaign at CERN
- Detector prototype is in good shape:
 - reliable operation
 - few dead channels, low noise
- Full software chain from raw to reconstructed data available
- First look into data looks promising
- Many analyses to follow...
