

H → invisible

Marcel Vos (IFIC, UV/CSIC Valencia)

Benchmarks: overview

- $e^+e^- \rightarrow ZH, Z \rightarrow \text{jets}, H \rightarrow \text{invisible}$ at 500 GeV
 - Important part of the physics case at 250 GeV
- Junping Tian
Yu Kato
- Depends on: jet energy resolution (+ISR, LS, ...)

Documents and publications

- Nothing published yet...
...even if $H \rightarrow$ inv. result at 250 GeV is obviously very important
- Regular communication between referee and analysis team
→ analysis team working very well and responding very quickly
- Yu prepared a draft note in Overleaf last week, with section titles and figures with 500 GeV results
- <https://www.overleaf.com/read/wckvhzcdqsrj>

Physics message

$\sqrt{s} = 250 \text{ GeV}$, $(P_{e^-}, P_{e^+}) = (-0.8, +0.3)$, $\int L dt = 900 \text{ fb}^{-1}$, Cut: No.1~No.7, DBD

$\sqrt{s} = 250 \text{ GeV}$, $(P_{e^-}, P_{e^+}) = (+0.8, -0.3)$, $\int L dt = 900 \text{ fb}^{-1}$, Cut: No.1~No.7, DBD

Gorgeous result at 250 GeV

Physics message

Figure 5: Full simulation result of recoil mass after event selection with Large detector

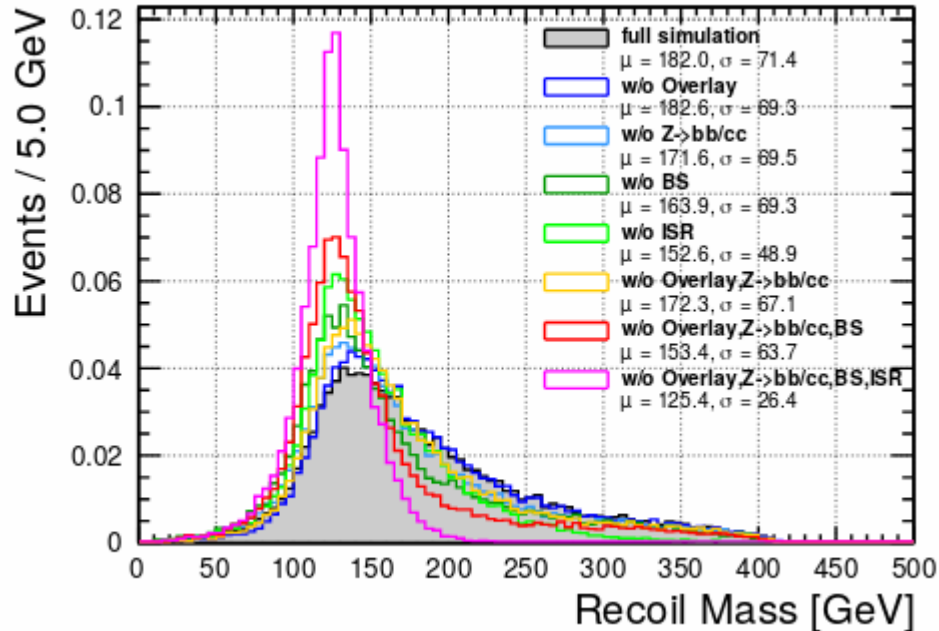

Much harder at 500 GeV
Indeed, limit on BR(H → inv.) 3 times worse

Analysis status

- Very detailed study of sources of degradation at 500 GeV has been performed

[qqh,h->invisible] iLCSoft: v02-00-02, $\sqrt{s} = 500$ GeV, Pol.: (-1.0,+1.0), mILD_l5_o1_v02

Rather large amount of cheating needed to become sensitive to detector design

- overlay may be tackled with a combination of removal and robust jet algorithms
- impact of neutrinos in heavy flavour decays may be tagged or corrected
- ISR harder to tackle (forward calorimetry)
- Luminosity spectrum impossible?

Analysis status

- As you have seen in the presentation, solid and interesting results exist
- Clear dependence on JER after a lot of cheating
- Note that 250 GeV raw result is much closer to cheated result

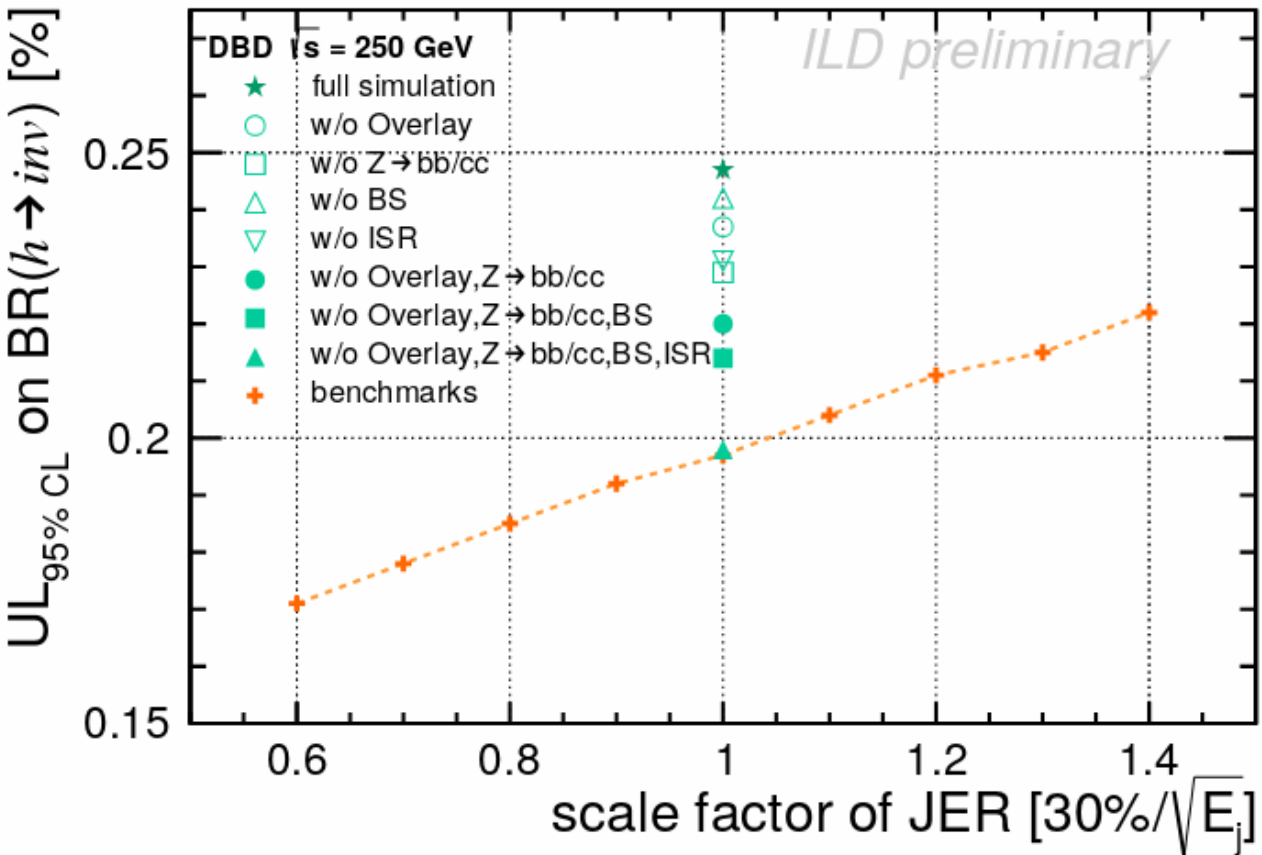

My favourite candidate plot for IDR

- include 250 GeV result?
- declutter by reducing number of cheating scenarios?

Benchmark results

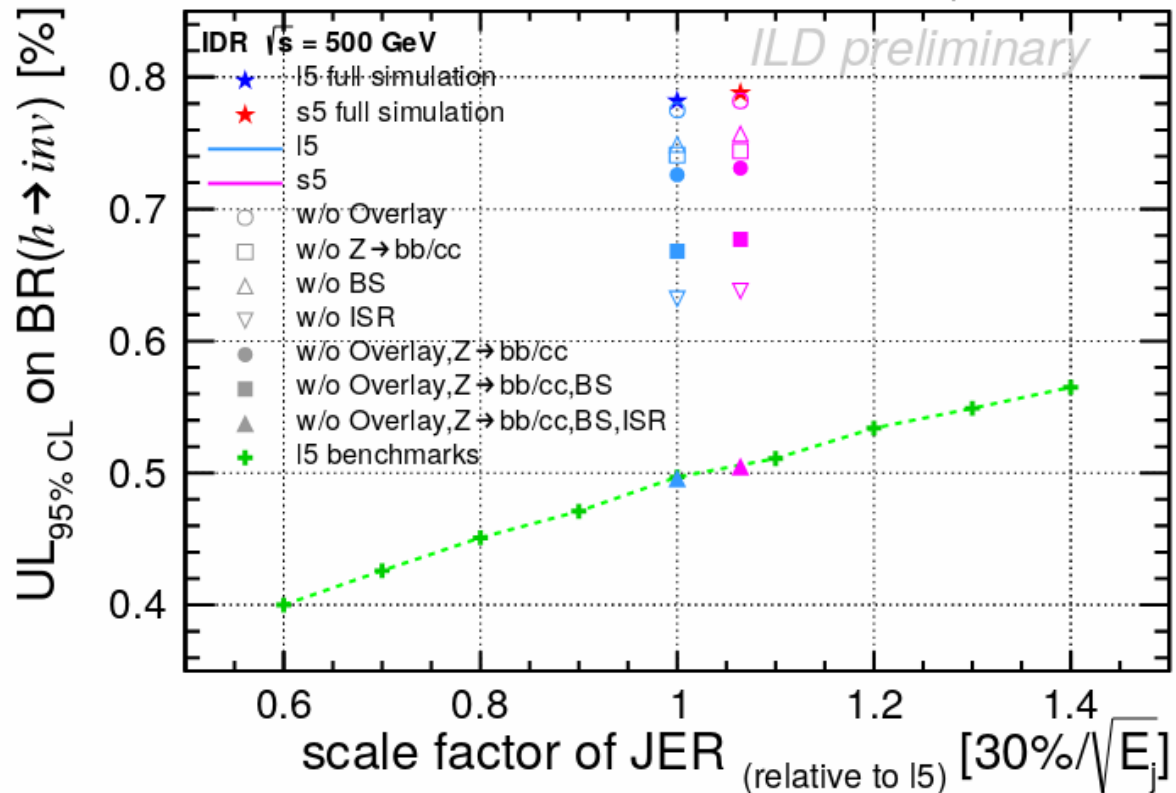

(25. Feb. 2019)

At 250 GeV:
0.2% (ideal) \rightarrow 0.24 (full)

Benchmark results

(25. Feb. 2019)

At 500 GeV:

L5: 0.49 (ideal) → 0.77 (full)

S5: 0.51 (ideal) → 0.79 (full)

Finalizing results

- About the contribution to the IDR
 - The jet energy resolution affects the result, but effect is marginal
 - We understand why the effect of the JER on 500 GeV analysis is less pronounced than naively expected
 - Breakdown of effects useful to define optimistic S2 scenario?

- Document the method in detail in its own publication
 - Detailed, high-profile publication about 250 GeV results
 - Draft exists for IDR backup note, time line compatible with IDR!
