- 3 Summary

Particle flow calorimetry

- Particle flow calorimetry: attempt to reconstruct visible final state particles from the information recorded by the detector.
- First result of Z mass resolution at 91 GeV with the Particle Flow Algorithm for the TESLA: 3.1 GeV [1] (ALEPH: 6 GeV).
- Jet energy resolution requirement at ILC: $\sigma_E/E = 3 \sim 4\%$ in the energy range from 50 to 500 GeV [2].
- Algorithms: Pandora [3], Arbor [4], Garlic [5] ...

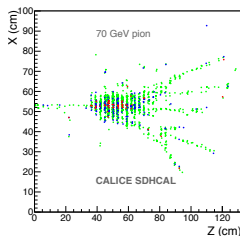

International Large Detector [6]

Semi-Digital HCAL

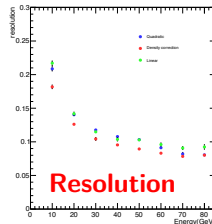

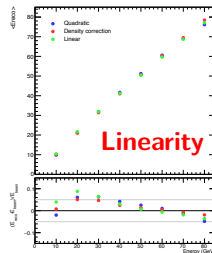

Two high granularity HCAL options at ILD

- Analog HCAL (AHCAL)
- Semi-Digital HCAL (SDHCAL [7]), implemented in ILD_I5_o2_v02.

SDHCAL prototype

- 48 layers, $6\lambda_I$
- RPC ($1 \times 1 m^2$)
- Pad: $1 \times 1 cm^2$
- Thresholds(pC): 0.11, 5, 15
- Power-pulsing
- Self-supporting structure.

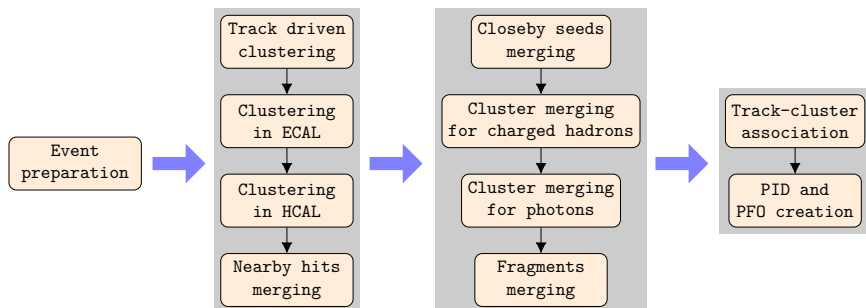

Outline

- 2 The particle flow algorithm of APRIL
- 3 Summary

Design of algorithm

- The name of this PFA: APRIL (Algorithm of Particle Reconstruction for the ILC developed in Lyon)
- Jet energy composition: charged particles: $\sim 60\%$; photons: $\sim 30\%$; neutral hadrons: $\sim 10\%$.

Related software

- Algorithms developed by using the **PandoraSDK** [8]
 - ▶ Multi-algorithm approach
 - ▶ Objects: track, hit, cluster, PFO
- **ILCSoft** (<https://github.com/iLCSoft>)
 - ▶ **Marlin** [9]
 - ▶ Geometry: ILD detector model (ILD_I5_o2_v02) implemented in **lcgeo**, which is based on **DD4hep** [10]
 - ▶ Digitizers of SDHCAL: SimDigital in **MarlinReco**)
 - ▶ **LCCalibration**: automated energy calibration for calorimeters at ILC (<https://github.com/iLCSoft/LCCalibration>).
- **mlpack** [11]: NeighborSearch, DBSCAN(Density-based spatial clustering of applications with noise).

Clustering

- Arbor [4] : use it as the algorithm for clustering the hits in calorimeter with tree topology.
- Nearby hits are linked by *connector*. The nearby hits are searched by the NeighborSearch (and NearbySearch) in mlpack [11].
- *Reference direction*

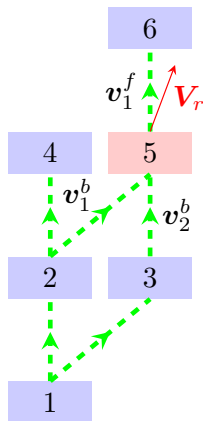

$$\mathbf{V}_r = w_b \times \sum_i \mathbf{v}_i^b + w_f \times \sum_j \mathbf{v}_j^f \quad (1)$$

- *Connector order*

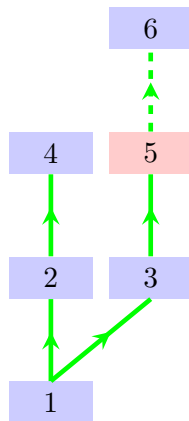

$$\kappa = \theta^{p_\theta} \times d^{p_d} \quad (2)$$

- Ambiguity: connector order at small angle, e.g., $\theta = 0$.
- Hits which are not clustered are dealt with by DBSCAN in mlpack.
- To restrain the error in clustering, the parameters are set to avoid forming big clusters.

Clustering (continued)

(a) Reference direction

(b) After clean

Cluster merging

- For cluster merging, the **order of cluster connection is proposed** for cluster merging in analog to $\kappa = \theta^{p_\theta} \times d^{p_d}$ in hit clustering, and the geometrical properties of cluster are utilized
 - ▶ Distances: COG distance; closest distance approach;
 - ▶ Angles: cluster axis; direction between clusters.
- The energy criteria for cluster merging
 - ▶ $\chi = (E_c - p_t)/\sigma_{E_c}$
 - ▶ σ_{E_c}
 - ★ HCAL: $0.55/\sqrt{E_c}$ for hadrons.
 - ★ ECAL: $0.15/\sqrt{E_c}$?
- Cluster merging is still under optimisation.

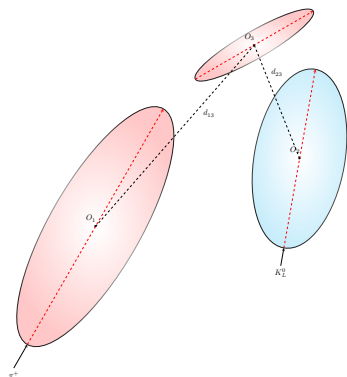

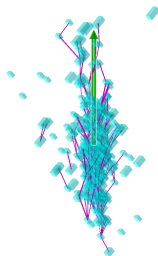

Figure: Merging between charged and neutral cluster.

Cluster properties

(a) Photon cluster

(b) Charged cluster

The center of gravity of a cluster

$$\mathbf{o} = \frac{1}{E} \sum_k e_k \mathbf{r}_k \quad (3)$$

The cluster axis is computed from the eigen vector of inertial tensor

$$I_{ij} = e_k \sum_k (\mathbf{r}_k^2 \delta_{ij} - \mathbf{r}_k^{(i)} \mathbf{r}_k^{(j)}) \quad (4)$$

Distance of clusters axes

- For two clusters, 1 and 2, the equation of their axes can be represented by

$$\mathbf{y}_i = \mathbf{o}_i + \lambda_i \mathbf{a}_i \quad (5)$$

where $i = 1, 2$; \mathbf{o}_i is the center of gravity as a reference to the points on the axis; \mathbf{a}_i is the direction of axis; λ_i is a free parameter which determines the position \mathbf{y}_i on the axis. The distance of the two axes (skew lines) is given by

$$d = |\mathbf{n} \cdot (\mathbf{o}_2 - \mathbf{o}_1)| \quad (6)$$

in which, $\mathbf{n} = (\mathbf{a}_1 \times \mathbf{a}_2) / |\mathbf{a}_1 \times \mathbf{a}_2|$.

- The cluster is used for fragment (*i.e.* the relatively small and far cluster form the main cluster) merging.

PFO creation

- Track-cluster association: position, direction and energy are considered.
- PID
 - ▶ γ , π^\pm , neutral hadron; More particle categories (such as muon, electron) is to be considered.
 - ▶ Shower profile, energy deposition and track information are used.

Figure: The reconstructed PFOs in an event of $E_{\text{CM}} = 91.2$ GeV.

Results

- Event samples: $e^+e^- \rightarrow q\bar{q}$, where $q = u, d, s$ ($|\cos\theta_q| < 0.7$)
- Detector model: ILD_I5_o2_v02
- Jet energy resolution, $\text{JER} = \frac{\text{RMS}_{90}(E_j)}{\text{Mean}_{90}(E_j)} = \sqrt{2} \cdot \frac{\text{RMS}_{90}(E_{jj})}{\text{mean}_{90}(E_{jj})}$
- JER at 91.2 GeV: APRIL: 4.2%; Pandora: 4.1%; Perfect PFA: 3.25%

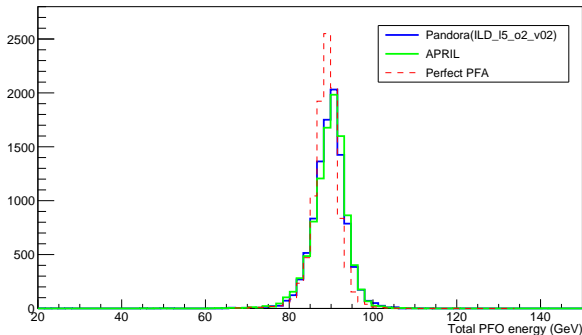

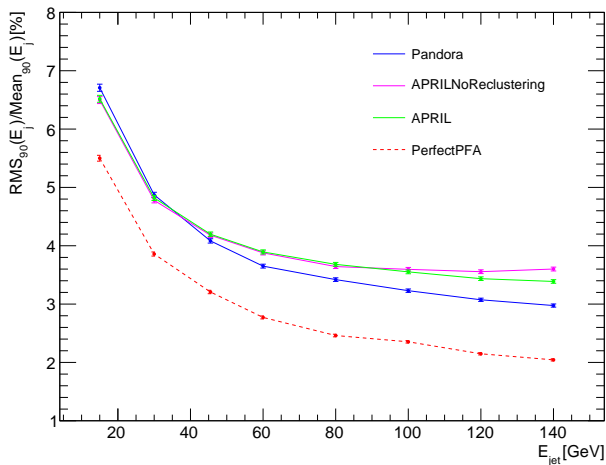

Figure: The energy of reconstructed PFO at $E_{\text{CM}} = 91.2$ GeV.

Results (continued)

- Error estimation of each step at $E_{\text{CM}} = 91.2 \text{ GeV}$

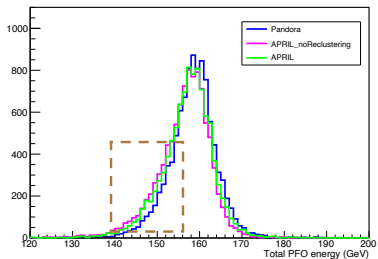

stage	error contribution
Clustering	$\sim 0.05\%$
Nearby hits merging	$\sim 0.15\%$
Cluster merging	$\sim 0.30\%$
Track-cluster association and PFO creation	$\sim 0.30\%$

Results (continued)

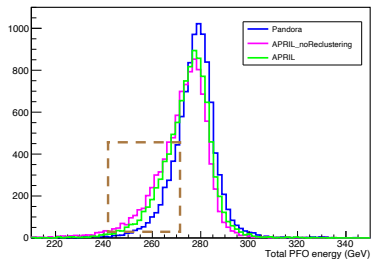

- A simple reclustering algorithm is tried for APRIL.

Simple reclustering

(a) 160 GeV

(b) 280 GeV

Outline

- 1 Introduction: Particle flow calorimetry and the ILD
- 2 The particle flow algorithm of APRIL
- 3 Summary

Summary

- A particle flow algorithm is developed in the framework of up-to-date ILCSOft.
- We proposed a cluster merging approach by constructing the cluster connection order from the computation of cluster geometrical properties.
- The code has great improvement from its first version, and the current result is quite close to our expectation.
- Plans
 - ▶ Optimisation: cluster merging, track-cluster association and PID.
 - ▶ Implementation: reclustering.
 - ▶ Far future: machine learning for PFA.
