Precision Electroweak Measurements with ILC250

Emphasis on Experimental Measurement Aspects Including $\sqrt{s}$, Polarization

Graham W. Wilson

University of Kansas

July 28, 2020

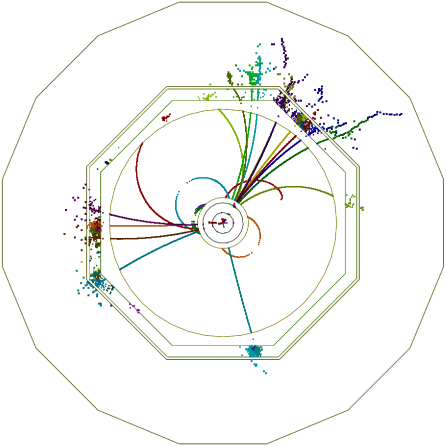
ILC is a unique and timely opportunity for understanding the electroweak scale

Many (physics, detector, and accelerator) opportunities to make it better!

More information on EWPO estimates - see arXiv:1908.11299
Study opportunities - see arXiv:2007.03650

Talk focus: Selected EW measurements with initial $\sqrt{s} \leq 250$ GeV stage

Outline



Physics Motivation

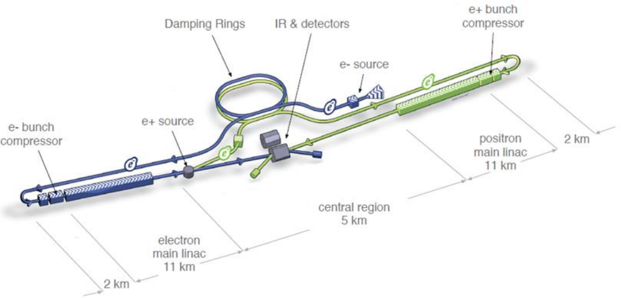
- Direct discovery of new physics would be wonderful. Many of us remain optimistic and work on such searches with LHC. $\mathrm{e^+e^-}$ colliders also have potential.
- Before the direct discoveries of the top quark and the Higgs boson, precision measurements of the then observable SM parameters pointed the way.
- Newer physics may continue to evade direct collider detection. Ultra-precise measurements of the fundamental SM parameters including the Higgs sector are especially compelling and can probe potentially much higher energy scales and associated new physics.
- How best to do this? The program needs to be flexible, timely, broad and probing of the underlying dynamics. Precision measurements at high energy, with full reconstruction of processes such as $\mathrm{W^+W^-}$ and $\mathrm{f\bar{f}}$. But also high precision measurements of other parameters at suitable $\sqrt{s}$ including top-threshold and Z-pole and potentially WW threshold with controlled systematics.
  Polarized beams (ILC strength - 4 colliders-in-1) give essential insight.
- The physics case for a future $\mathrm{e^+e^-}$ collider is very well established. Let's seize this opportunity and explore the physics (preferably in our lifetime).

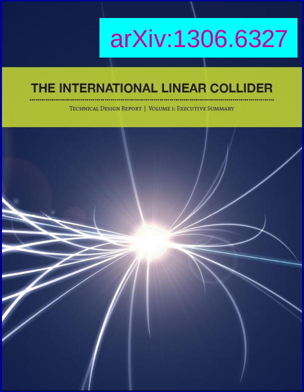
$\mathrm{e^+e^-}$ Linear Colliders

Linear colliders are the only practical way with $\mathrm{e^+e^-}$ to go significantly above the top pair threshold (synchrotron radiation and real-world economics)

- ILC is based on superconducting RF (mature and power efficient)
  - Under study and development for many years
  - World-wide consensus in 2001 as the next future collider
  - Fully international project with strong participation from US, Europe and Asia
  - Technology deployed in many facilities: XFEL, LCLS-II
- ILC TDR 2013 - focus on engineered design capable of $\sqrt{s} = 200 - 500$ GeV upgradable to 1 TeV and potentially beyond
  - longitudinally polarized electron (80%) and positron (30%) beams
  - Japan is exploring hosting the ILC as a global project
  - With the Higgs discovery - can guarantee a rich physics program
- In recent years → a focus on getting started as soon as possible at $\sqrt{s} = 250$ GeV while retaining energy extensibility
  - Optimized design for $\sqrt{s} = 250$ GeV with higher luminosity
  - Now also have easily achievable running with polarized beams at lower energies including $\sqrt{s} \approx M_{\mathrm{Z}}$ with $L = 4.2 \times 10^{33}\ \mathrm{cm^{-2}s^{-1}}$
  - New appreciation in Japan of the longer-term opportunities with higher energy

International Linear Collider Project

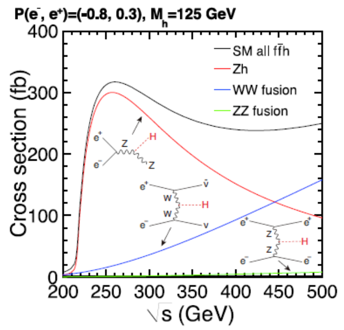




arXiv:1306.6327

THE INTERNATIONAL LINEAR COLLIDER

TECHNICAL DESIGN REPORT | VOLUME 1: EXECUTIVE SUMMARY

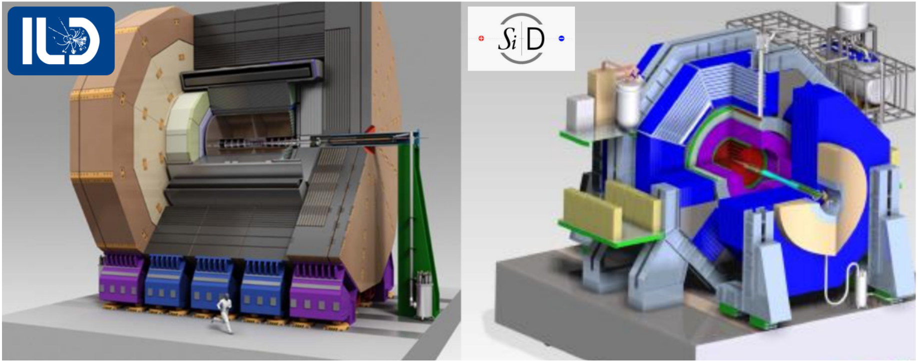


ILC Detectors

Described in arXiv:1306.6329.

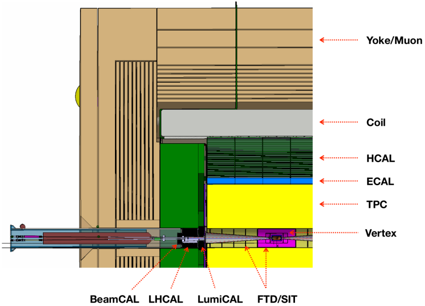
ILD = International Large Detector
(updated arXiv:2003.01116 (IDR))

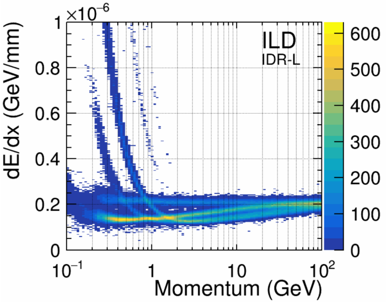
SiD = Silicon Detector



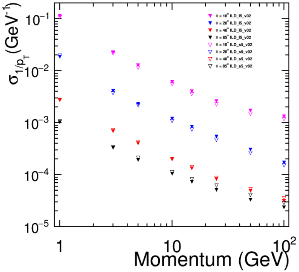
Modern detectors designed for ILC (B=3.5-5 T).
Particle-flow for jets. Very hermetic. Low material. Precision vertexing.
ILD centered around a TPC. SiD - all silicon tracking.

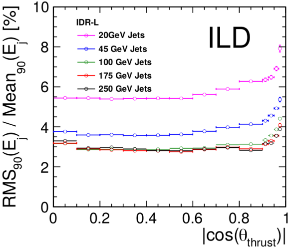
ILD Detector (See IDR and T. Tanabe talk)

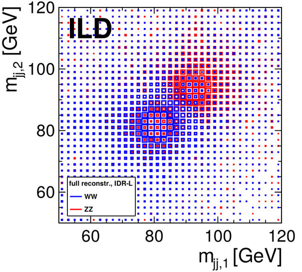




Momentum Resolution



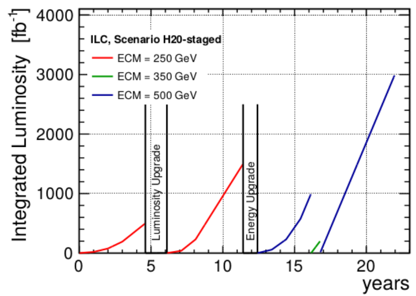




ILC Parameters / Running Scenarios

J. Brau et al., arXiv: 1506.07830

Updated in 1903.01629



- Baseline scenario for study
- Run plan flexible - will evolve informed by future developments
- Future upgrade to 1 TeV and potentially beyond
- Options for dedicated running with polarized beams at Z-pole (100 fb^{-1}) and WW threshold (500 fb^{-1}).

	integrated luminosity with $\mathrm{sgn}(P(e^-),P(e^+))$ =			
	(-,+)	(+,-)	(-,-)	(+,+)

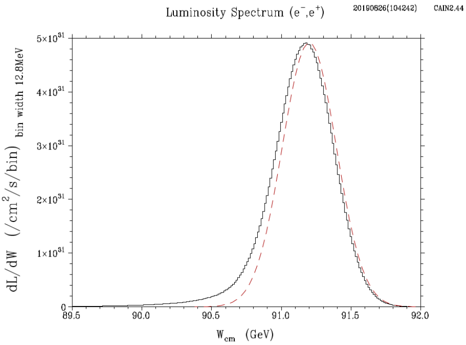
ILC running below $\sqrt{s} = 250$ GeV ?

Always foreseen as an “option” that should be justifiable by the physics du jour

- ILC TDR design focused on $\sqrt{s} > 200$ GeV
- Luminosity naturally scales with γ at a linear collider
- Now have a design that leads to $L = 4.2 \times 10^{33} \mathrm{cm}^{-2}\mathrm{s}^{-1}$ at $\sqrt{s} = 91$ GeV with polarized beams (see arXiv:1908.08212 by Yokoya, Kubo and Okugi [3])
- Enables a broader program of electroweak measurements
- High statistics Z samples for detector calibration and alignment, and hadronization modeling



How well can this be used?
Control systematics?
$100\ \mathrm{fb}^{-1}$ polarized corresponds to 4.2×10^9 hadronic events and 2.0×10^8 dimuons. FWHM is about 500 MeV (beam momentum spread + beamstrahlung). Lots of fun questions to explore.

$\mu^+\mu^-$/Z ubiquity (in $\sqrt{s}$ scale discussion)

"$\mu^+\mu^-$" or "Z" appears in many places - for varied, but related purposes.

1. Full energy $\mu^+\mu^-$: $\mathrm{e^+e^-} \to \mu^+\mu^-$ with little ISR ($s' \approx s \gg M_{\mathrm{Z}}^2$)
2. Radiative return $\mu^+\mu^-$: $\mathrm{e^+e^-} \to \mu^+\mu^-\gamma(\gamma)$ with lots of ISR ($s \gg s' \approx M_{\mathrm{Z}}^2$). The photon(s) may or may not be detected.
3. Z-pole $\mu^+\mu^-$: $\mathrm{e^+e^-} \to \mu^+\mu^-$ with $\sqrt{s}$ near M_{Z}
4. $J/\psi \to \mu^+\mu^-$: A common source of J/ψ is from $\mathrm{Z} \to \mathrm{b\overline{b}}$.

Why?

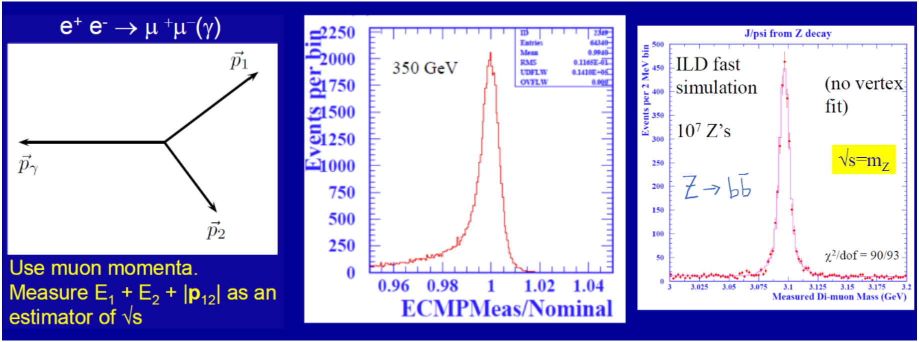
- The old method of choice for $\sqrt{s}$ estimation at ILC was to use radiative return $\mu^+\mu^-$ and angle-based reconstruction. Robust - but suffers statistically due to $\Gamma_{\mathrm{Z}}/M_{\mathrm{Z}}$ and relies on M_{Z} (23 ppm)
- New method for $\sqrt{s}$ estimation uses all $\mu^+\mu^-$ (both full energy, intermediate energy, radiative return) to form a muon-momentum based estimator, $\sqrt{s}_{\mathrm{P}}$.
- In turn $\sqrt{s}_{\mathrm{P}}$ needs the tracker momentum-scale to be calibrated to high precision. Principally use $J/\psi \to \mu^+\mu^-$ for this. Z running is very helpful.
- Given the 0.15% tracker momentum resolution, Z-pole $\mu^+\mu^-$, can also be used to measure $\sqrt{s}$ for Z-pole runs (limited by 1.9 ppm $m_{J/\psi}$ knowledge).

Center-of-Mass Energy Measurement

Critical input for $M_{\rm t}$, $M_{\rm W}$, $M_{\rm H}$, $M_{\rm Z}$, $M_{\rm X}$ measurements

1. Standard precision of $\mathcal{O}(10^{-4})$ in $\sqrt{s}$ for $M_{\rm t}$ straightforward
2. Targeting precision of $\mathcal{O}(10^{-5})$ in $\sqrt{s}$ for $M_{\rm W}$ given likely systematics
3. For $M_{\rm Z}$ - helps to do even better

Use muon momenta method. Tie p to the J/ψ mass scale (1.9 ppm uncertainty).



Use muon momenta.
Measure $E_1 + E_2 + |\mathbf{p}_{12}|$ as an estimator of $\sqrt{s}$

Measure $<\sqrt{s}>$ and lumi. spectrum simultaneously. Expect statistical uncertainty of 1.0 ppm on p-scale per 1200k $J/\psi \to \mu^+\mu^-$ (4×10^9 hadronic Z's).

Momentum Scale Calibration (essential for $\sqrt{s}$)

Most obvious is to use $J/\psi \to \mu^+\mu^-$. But event rate is limited.

Particle	$n_{Z\mathrm{had}}$	Decay	BR (%)	$n_{Z\mathrm{had}} \cdot$ BR	Γ/M	PDG ($\Delta M/M$)
J/ψ	0.0052	$\mu^+\mu^-$	5.93	0.00031	3.0×10^{-5}	1.9×10^{-6}

Candidate particles for momentum scale calibration and abundances in Z decay

Sensitivity of mass-measurement to p-scale (α) depends on daughter masses and decay

$$m_{12}^2 = m_1^2 + m_2^2 + 2p_1p_2\left[(\beta_1\beta_2)^{-1} - \cos\psi_{12}\right]$$

Particle	Decay	$<\alpha>$	max α	σ_M/M	$\Delta p/p$ (10 MZ)	$\Delta p/p$ (GZ)	PDG limit
J/ψ	$\mu^+\mu^-$	0.99	0.995	7.4×10^{-4}	13 ppm	1.3 ppm	1.9 ppm
K^0_S	$\pi^+\pi^-$	0.55	0.685	1.7×10^{-3}	1.2 ppm	0.12 ppm	38 ppm
Λ	$\pi^-\mathrm{p}$	0.044	0.067	2.6×10^{-4}	3.7 ppm	0.37 ppm	80 ppm
D^0	$\mathrm{K}^-\pi^+$	0.77	0.885	7.6×10^{-4}	2.4 ppm	0.24 ppm	30 ppm

Estimated momentum scale statistical errors ($p_X = 20$ GeV)

Use of J/ψ would decouple $\sqrt{s}$ determination from M_Z knowledge.

Opens up improved M_Z and Γ_Z measurements. (B-field map, alignment, material etc.)

Longitudinally Polarized Beams

ILC baseline design has e^- polarized to 80%, e^+ to 30%

- $P_{\mathrm{e}^-} = 90\%$ is not out of the question
- $P_{\mathrm{e}^+} = 60\%$ is under study, would add significant value, and may be feasible

In contrast to circular colliders, longitudinal polarization is easier and not expected to cost luminosity.

$$\begin{aligned}\sigma(P_{\mathrm{e}^-}, P_{\mathrm{e}^+}) &= \frac{1}{4}\{(1-P_{\mathrm{e}^-})(1+P_{\mathrm{e}^+})\sigma_{LR} + (1+P_{\mathrm{e}^-})(1-P_{\mathrm{e}^+})\sigma_{RL} + \\ &\qquad (1-P_{\mathrm{e}^-})(1-P_{\mathrm{e}^+})\sigma_{LL} + (1+P_{\mathrm{e}^-})(1+P_{\mathrm{e}^+})\sigma_{RR}\}\end{aligned}$$

where σ_k ($k =$ LR, RL, LL and RR) are the fully polarized cross-sections.

With both beams polarized it is **straightforward** to measure the absolute polarization of both beams *in situ* when $\sigma_{LL} = \sigma_{RR} = 0$ (such as γ/Z exchange). Using 4 cross-section measurements from the $(-+, +-, --, ++)$ helicity combinations, solve for 4 unknowns (σ_U, A_{LR}, P_{e^-}, P_{e^+}). Assumes same $|P|$ for $+$ and $-$ helicity of same beam. Need to dedicate some $\mathcal{L}$ to “un-interesting” $(--, ++)$ configurations.

Supplement with polarimeters to track relative polarization changes.
(Also can use $\mathrm{W}^+\mathrm{W}^-$ etc at high $\sqrt{s}$)

W Mass

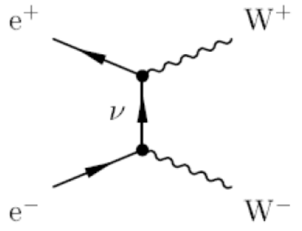
M_{W} is an experimental challenge. Especially so for hadron colliders.

The four most promising approaches to measure M_{W} at an e^+e^- collider are:

1. Polarized Threshold Scan Measurement of the $\mathrm{W^+W^-}$ **cross-section** near **threshold** with longitudinally **polarized** beams. Unique ILC potential.
2. Constrained Reconstruction Kinematically-constrained reconstruction of $\mathrm{W^+W^-}$ using constraints from **four-momentum conservation** and optionally mass-equality as was done at LEP2.
3. Hadronic Mass Direct measurement of the **hadronic mass**. This can be applied particularly to single-W events decaying hadronically or to the hadronic system in semi-leptonic $\mathrm{W^+W^-}$ events.
4. Leptonic Observables Use lepton **endpoints** in semi-leptonic and fully leptonic $\mathrm{W^+W^-}$ events with either $\mathrm{W} \rightarrow \mathrm{e}\nu_e$ or $\mathrm{W} \rightarrow \mu\nu_\mu$. Use **pseudomasses** in dileptons.

Method 1 needs dedicated running near $\sqrt{s} = 161$ GeV. Methods 2, 3, and 4 can exploit the standard $\sqrt{s} \geq 250$ GeV ILC program (deserve more study). Methods 1, 2, and 4 rely on $\sqrt{s}$ scale systematic control. Target 2 MeV uncertainty on M_{W}.

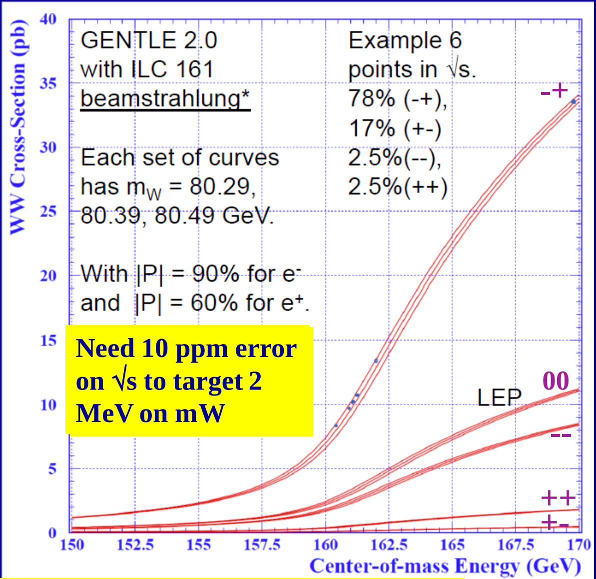
ILC Polarized Threshold Scan



Use (-+) helicity combination of e^- and e^+ to enhance WW.

Use (+-) helicity to suppress WW and measure background.

Use (--) and (++) to control polarization (also use 150 pb Z-like events)



GENTLE 2.0
with ILC 161
beamstrahlung*

Each set of curves has m_W = 80.29, 80.39, 80.49 GeV.

With |P| = 90% for e^- and |P| = 60% for e^+.

Example 6 points in √s.
78% (-+),
17% (+-)
2.5%(--),
2.5%(++)

Need 10 ppm error on √s to target 2 MeV on mW

Experimentally very robust. Measure pol., bkg. in situ

Results from updated ILC study (arXiv:1603.06016)

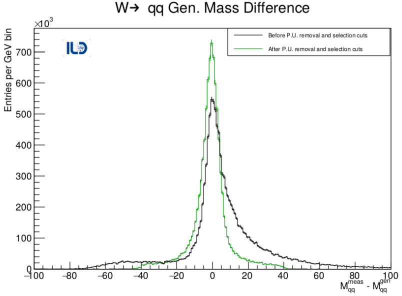
Total M_{W} experimental uncertainty (MeV)

With 10 ppm assumed uncertainty on $\sqrt{s}$ near WW threshold, additional contribution of 0.8 MeV on M_{W}

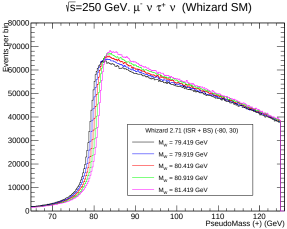
Fit essentially includes experimental systematics. Main one - **background** determination.

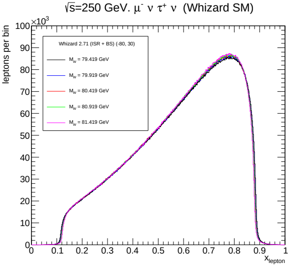
$$\Delta M_{\mathrm{W}}(\mathrm{MeV}) = 2.4\,(\mathrm{stat}) \oplus 3.1\,(\mathrm{syst}) \oplus 0.8\,(\sqrt{\mathrm{s}}) \oplus \mathrm{theory}$$

$M_{\rm W}$, $\Gamma_{\rm W}$ from higher energy runs



$W^+W^- \to q\bar{q}\ell\nu$ ($\ell = e, \mu, \tau$) study (J. Anguiano (KU)), using **hadronic mass**. Statistical sensitivity of 2.4 MeV on $M_{\rm W}$ for 1.6 $\rm ab^{-1}$ (-80%, +30%) at $\sqrt{s} = 500$ GeV based on full simulation including overlay. Can be improved, but $m_{\rm had}$-only measurement will likely be limited by systematics like JES. Expect improvements with **constrained fit** and $\sqrt{s} = 250$ GeV data set.





Di-lepton **pseudomass** and lepton **endpoint** distributions. *Plots to be cleaned up ...*

Sensitive to $M_{\rm W}$.

Stat. uncertainty of 4.4 MeV on $M_{\rm W}$ for 2.0 $\rm ab^{-1}$ (45,45,5,5) at $\sqrt{s} = 250$ GeV. **Leptonic observables** (shape-only), x_ℓ, M_+, M_- (GWW) Exptl. systematics should be small.

Polarization Observables

At a polarized $\mathrm{e^+e^-}$ collider, A_e is given by the left-right asymmetry in the total rate for Z production,

$$A_e = A_{LR} \equiv \frac{\sigma_L - \sigma_R}{(\sigma_L + \sigma_R)} \ ,$$

where σ_L and σ_R are the cross section for 100% polarized $e_L^- e_R^+$ and $e_R^- e_L^+$ initial states. For other asymmetries, beam polarization can also play a role. These quantities are measured from the left-right forward-backward asymmetry

$$A^f_{FB,LR} \equiv \frac{(\sigma_F - \sigma_B)_L - (\sigma_F - \sigma_B)_R}{(\sigma_F + \sigma_B)_L + (\sigma_F + \sigma_B)_R} \ ,$$

where, again, L and R refer to states of 100% polarization. At the tree level,

$$A^f_{FB,LR} = \frac{3}{4} A_f \ .$$

For unpolarized/polarized collider, the A_f values can again be obtained from quantities such as the forward-backward asymmetry using charge-identified fermion $\frac{d\sigma}{d\cos\theta}$

$$A^f_{FB} \equiv \frac{(\sigma_F - \sigma_B)}{(\sigma_F + \sigma_B)} = \frac{[(\sigma_F)_L + (\sigma_F)_R] - [(\sigma_B)_L + (\sigma_B)_R]}{[(\sigma_F)_L + (\sigma_F)_R] + [(\sigma_B)_L + (\sigma_B)_R]} = \frac{3}{4} A_e A_f \ ,$$

A_{LR} at $\sqrt{s} = M_{\mathrm{Z}}$

Studied initially by K. Mönig 1999
For $\mathrm{Z} \to \mathrm{f\bar{f}}$, general cross-section formula simplifies to

$$\sigma = \sigma_u[1 - P^+P^- + A_{\mathrm{LR}}(P^+ - P^-)]$$

With four combinations of helicities, 4 equations in 4 unknowns. Can solve for A_{LR} in terms of the four measured cross-sections (assumes helicity reversal for each beam maintains identical absolute polarization).

$$\begin{aligned}
\sigma_{++} &= \sigma_u[1 - P^+P^- + A_{\mathrm{LR}}(P^+ - P^-)] \\
\sigma_{-+} &= \sigma_u[1 + P^+P^- + A_{\mathrm{LR}}(-P^+ - P^-)] \\
\sigma_{+-} &= \sigma_u[1 + P^+P^- + A_{\mathrm{LR}}(P^+ + P^-)] \\
\sigma_{--} &= \sigma_u[1 - P^+P^- + A_{\mathrm{LR}}(-P^+ + P^-)]
\end{aligned}$$

For $P^- = 0.8$, $P^+ = 0.6$, $f_{\mathrm{SS}} = 0.08$, $\sigma_U^{vis} = 33$ nb:

$$\Delta A_{\mathrm{LR}}(\mathrm{stat}) = 1.7 \times 10^{-5} / \sqrt{\mathrm{L}(100\ \mathrm{fb}^{-1})}$$

A_{LR} Systematics

Statistical Systematics

Source		Multiplicative Factor
Bhabha Statistics	relative L ($\sigma_{\mathrm{Bhabha}} = 250$ nb)	1.09
Compton Statistics	relative P of opposite helicity	1.34

Center-of-mass Energy

$dA_{\mathrm{LR}}/d\sqrt{s} = 2.0 \times 10^{-2}$ GeV^{-1}. 5 ppm (see next slide) on $\sqrt{s} \Rightarrow 0.9 \times 10^{-5}$ on A_{LR}

Beamstrahlung

Depends on machine. Previous study (TESLA) estimated a change in A_{LR} of 9×10^{-4}. Assume known to 1% $\Rightarrow 0.9 \times 10^{-5}$ on A_{LR}

$$\Delta A_{\mathrm{LR}}(10^{-5}) = 2.4/\sqrt{L(100\ \mathrm{fb}^{-1})}\ (\mathrm{stat})\ \oplus 0.9\ (\sqrt{\mathrm{s}})\ \oplus 0.9(\mathrm{BS})$$

Can target experimental precision on A_{LR} of 3×10^{-5} with 100 fb^{-1}. Oft-cited 10^{-4} prospect (1.3×10^{-5} on $\sin^2\theta^{\ell}_{\mathrm{eff}}$) with 30 fb^{-1} well within reach (it was conservative). Note that $\sin^2\theta^{\ell}_{\mathrm{eff}}$ interpretation depends amongst others on improved knowledge of $\Delta\alpha_{\mathrm{had}}$.

Polarized Observables with Radiative Return Events

See 1908.11299 for details. Use jet polar angles to infer longitudinal boost, β.

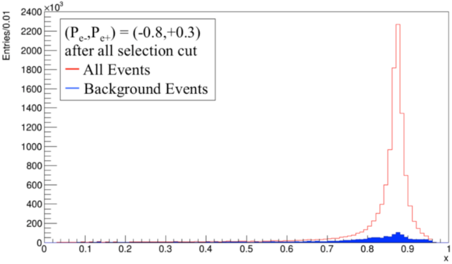


Figure 2: Reconstructed distribution of $x \equiv \frac{2|\beta|}{1+|\beta|}$ for the signal $e^+e^- \to \gamma Z$, $Z \to q\bar{q}$ and from background events that mimic this signal, at $\sqrt{s} = 250$ GeV with an integrated luminosity of 250 fb^{-1}.

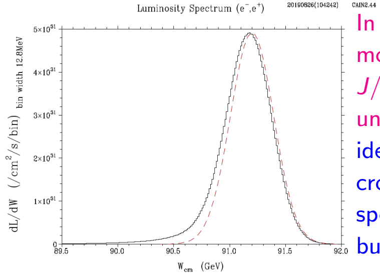
Study indicates statistical uncertainty on A_e of 14×10^{-5} with full 2 ab^{-1} of ILC250 running.

Very different systematics to Z-pole based A_{LR} measurement and accessible with data collected synergystically with Higgs production. Nevertheless, Z-pole running precision expected to be superior.

Center-of-mass Energy Calibration around the Z-Pole

Expected lumi. spectrum at the Z, has a FWHM of about 500 MeV ($\sigma \approx 215$ MeV). Tracker momentum resolution per muon is 0.15% (88 MeV on $\sqrt{s}$). Leads to an average stat. uncertainty per di-muon event of ≈ 230 MeV. So one can measure the average $\sqrt{s}$ with a stat. uncertainty of 0.18 ppm with the 100 fb^{-1} A_{LR} optimized run at M_{Z} (2×10^8 $\mathrm{e}^+\mathrm{e}^- \to Z \to \mu^+\mu^-$).

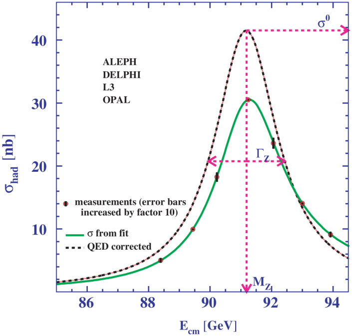


In the same data taking, one can measure the tracker momentum scale with 1.0 ppm stat. uncertainty using $J/\psi \to \mu^+\mu^-$, more than saturating the 1.9 ppm syst. uncertainty from the known J/ψ mass. Note that the idea is to collect Z events and use these to measure cross sections & asymmetries, C-o-M energy/lumi spectrum and *p*-scale simultaneously. Potentially even bunch-by-bunch under the exact same conditions.

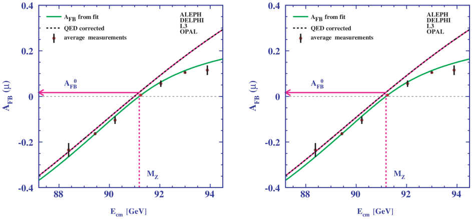
With an overall momentum scale uncertainty target at the 2.5 ppm level (earlier assumption of 10 ppm was sufficient for the M_{W} target) potentially within reach, one should seek to improve on the current 23 ppm uncertainty on M_{Z}. Uncertainties on M_{Z} as low as 230 keV are presumably thinkable (2.5 ppm).

Polarized Beams Z Scan for Z LineShape and Asymmetries

Essentially, redo LEP-style measurements in all channels but also with $\sqrt{s}$ dependence of the polarized asymmetries, A_{LR} and $A^{f}_{FB,LR}$, in addition to A_{FB}.



LEP: $\Delta M_{\mathrm{Z}} = 2.1$ MeV, $\Delta\Gamma_{\mathrm{Z}} = 2.3$ MeV



With unoptimized, 100 fb^{-1} polarized 5-point scan, (0, ±1, ±2) GeV around M_{Z}, **statistical** uncertainties on M_{Z} of 40 keV and Γ_{Z} of 90 keV from LEP-style fit to $(M_{\mathrm{Z}}, \Gamma_{\mathrm{Z}}, \sigma^0_{\mathrm{had}}, R^0_e, R^0_\mu, R^0_\tau)$ using ZFITTER 6.42 for QED convolution.

Exploiting this needs in-depth study of $\sqrt{s}$ calibration systematics + maybe improved energy-spread. ILC $\mathcal{L}$ is sufficient for M_{Z}. Γ_{Z} systematic uncertainty depends on $(\sqrt{s}_{+} - \sqrt{s}_{-})$ uncertainty rather than absolute $\sqrt{s}$ scale, so expect $\Delta\Gamma_{\mathrm{Z}} < \Delta M_{\mathrm{Z}}$.

Higher Energy: Triple Gauge Couplings (WWγ, WWZ)

Many 4f processes besides $\mathrm{W^+W^-}$. "Single-W" processes, $\mathrm{e^+e^-} \rightarrow \mathrm{W\ e\ }\nu_e$, very important. Can disentangle the beam polarizations, $P_{\mathrm{e^-}}$ and $P_{\mathrm{e^+}}$, and constrain residual imperfect spin-flip, using such processes where σ_{LL} or $\sigma_{RR} \neq 0$.

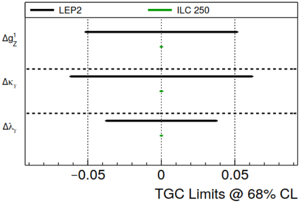
$\rho(\kappa_A, \lambda_A)$	35.4	35.4	35.4	35.4

Table 13: Projected statistical errors, in %, for $e^+e^- \rightarrow W^+W^-$ measurements input to our fits. The errors are quoted for luminosity samples of 500 fb^{-1} divided equally between beams with -80% electron polarisation and +30% positron polarisation and brams with +80% electron polarisation and -30% positron polarisation. Please see the text of Appendix B for further explanation of this table.

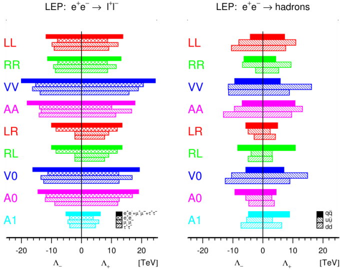


3-parameter fits based on full simulation studies and their extrapolation with ILD. Clearly higher energy is better especially given the γ scaling of luminosity. Already with ILC250 (2 ab^{-1}), expect 0.05% precision, compared to 5% precision for a LEP2 experiment. No comparable hadron collider results available. See thesis by Robert Karl (DESY) with work on a multi-channel global fit including correlations.

Two-Fermions and Four-Fermion Contact Interactions

See LEP2 studies with cross-sections and A_{FB} / (ILC adds $A_{LR}, A^{f}_{FB,LR}$)

$$\mathcal{L}_{\text{eff}} = \frac{g^2}{(1+\delta)\Lambda^2_{\pm}} \sum_{i,j=L,R} \eta_{ij}\bar{e}_i\gamma_\mu e_i \bar{f}_j \gamma^\mu f_j,$$



LEP2

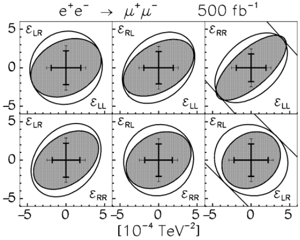


Fig. 1. Two-dimensional projections of the 95% C.L. allowed region (27) for $e^+e^- \to \mu^+\mu^-$ at $\mathcal{L}_{\text{int}} = 50\ \text{fb}^{-1}$ and $\mathcal{L}_{\text{int}} = 500\ \text{fb}^{-1}$. Note that the scales are different. $|P_e| = 0.8$, $|P_{\bar{e}}| = 0.0$ (outer ellipse) and $|P_{\bar{e}}| = 0.6$ (inner ellipse). The solid crosses represent the 'one-parameter' bounds under the same conditions.

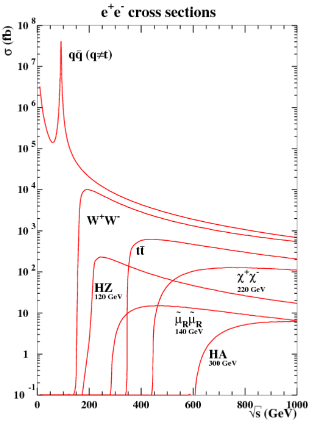
At ILC, can follow a more model independent approach. Example Ref. 2. Polarization gives access to full 4-parameter space (LR,RL,LL,RR).

Current ILC projections - see arXiv:1908.11299 extend to 151 to 478 TeV for Λ in various models (driven by 8 ab^{-1} at 1 TeV).

Detector Calibration and Alignment

Clean $\mathrm{e}^+\mathrm{e}^-$ environment. But particle-based calibration at high $\sqrt{s}$ has



Challenges

- cross-sections
- duty-cycle (power-pulsing)
- "push-pull"
- seismic tolerance
- thermal issues
- unprecedented precision goals

Part of the solution

Accelerator capable of "calibration runs" at the Z with reasonable luminosity. Z running is the most statistically effective way to calibrate the detector. May be essential to fully exploiting the ILC at all $\sqrt{s}$. Design this capability in!

Now done!

Summary

- ILC can advance greatly our knowledge of electroweak precision physics.
- Polarized electron and **positron** beams are a unique asset.
- Can deliver much more rigorous test of the SM which explores new physics. Highlighted by top mass measurement and

$$\Delta M_{\mathrm{W}} = 2 - 3\,\mathrm{MeV}$$

$$\Delta A_{\mathrm{LR}}(10^{-5}) = 2.4/\sqrt{L(100\ \mathrm{fb}^{-1})}\,(\mathrm{stat})\ \oplus 0.9\,(\sqrt{\mathrm{s}})\ \oplus 0.9(\mathrm{BS})$$

- Scope for best M_{W} measurements from standard ILC running.
- Experimental strategies for controlling systematics associated with $\sqrt{s}$, polarization, luminosity spectrum are worked out.
- Momentum scale is a key. Enabled by precision low material tracker. Promises to also open up precision measurement advances for M_{Z}, Γ_{Z}, etc
- More study on expt./acc. systematics + tracker design work necessary.
- An accelerator is needed! On-going very encouraging developments in Japan.
- The physics discussed here benefits greatly given that the accelerator is now designed to include efficient running at lower $\sqrt{s}$.

WEIGHTED AVERAGE
493.677±0.013 (Error scaled by 2.4)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

			χ^2
DENISOV	91	CNTR	7.7
GALL	88	CNTR	13.6
LUM	81	CNTR	
BARKOV	79	EMUL	0.1
CHENG	75	CNTR	1.0
BACKENSTO...	73	CNTR	0.1
			22.4

(Confidence Level = 0.0002)

An example of something, not so far from being fundamental with a big inconsistency. Accuracy is as important as precision. Important to measure particles with different methods if there are actually residual misunderstood systematics (examples top, W, Higgs, Z).

With ILC detectors and precision momentum-scale calibration, ILC should be able to help resolve this! This would also help lots of D, B masses etc.

Maybe worth doing a careful study of how to improve this with colliders.

Hadronization Systematics

How does a W, Z, H, t decay hadronically?

Models like PYTHIA, HERWIG etc have been tuned extensively to data. Not expected to be a complete picture.

Inclusive measurements of **identified particle rates** and **momenta spectra** are an essential ingredient to describing hadronic decays of massive particles.

ILC could provide comprehensive measurements with up to 1000 times the published LEP statistics and with a much better detector with Z running.

High statistics with W events.

Why?

Measurements based on hadronic decays, such as hadronic mass, jet directions underlie much of what we do in energy frontier experiments.

Key component of understanding jet energy scales and resolution.

Important to also understand flavor dependence: u-jets, d-jets, s-jets, c-jets, b-jets, g-jets.

Full Simulation + Kalman Filter

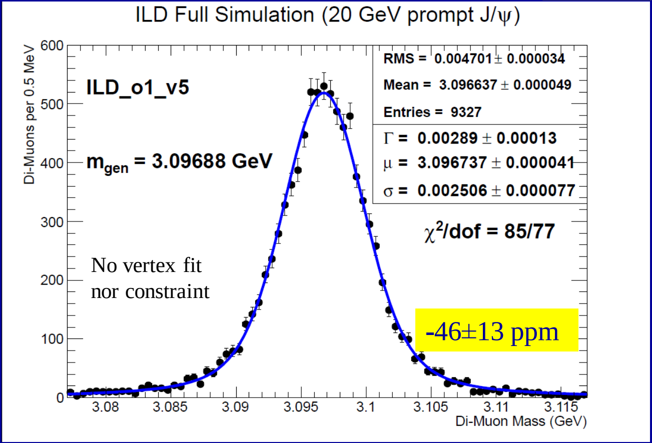
$\sqrt{s}=m_Z$

10k “single particle events”

Work in progress – likely need to pay attention to issues like energy loss model and FSR.

Preliminary statistical precision similar.

More realistic material, energy loss and multiple scattering.



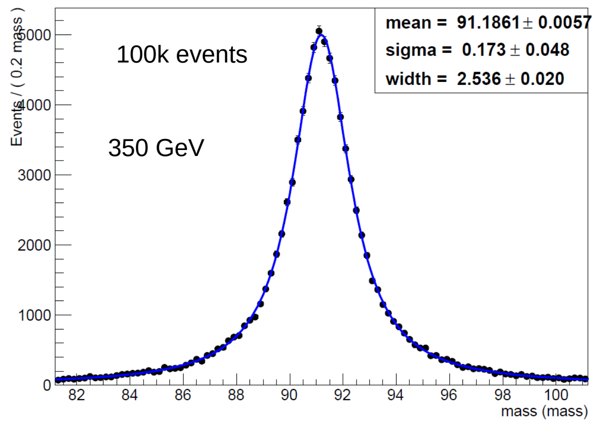
No vertex fit nor constraint

-46±13 ppm

Empirical Voigtian fit.

Need consistent material model in simulation AND reconstruction

Can control for p-scale using measured di-lepton mass



This is about 100 fb^{-1} at ECM=350 GeV.

Statistical sensitivity if one turns this into a Z mass measurement (if p-scale is determined by other means) is

1.8 MeV / √N

With N in millions.

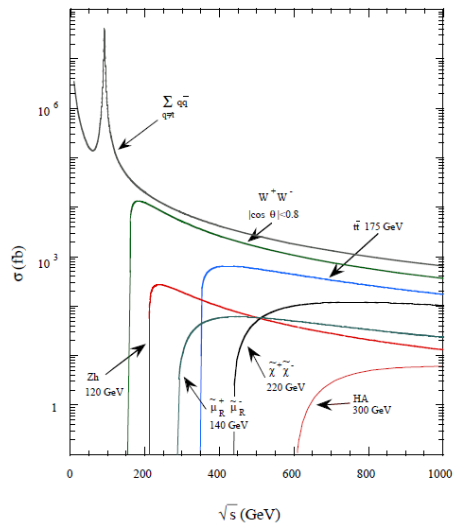
Alignment ?
B-field ?
Push-pull ?
Etc …

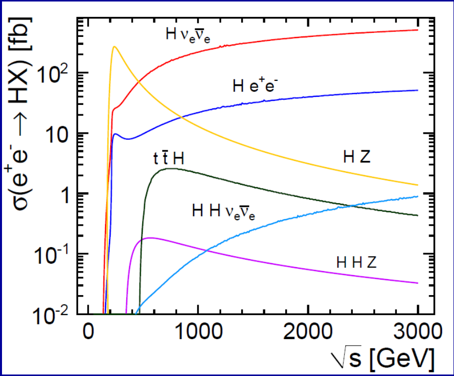
XFEL at DESY

Experimentation with ILC

- Physics experiments with e^+e^- colliders are **very different** from a hadron collider.
- Experiments and detectors can be **designed without the constraints** imposed by triggering, radiation damage, pileup.
- **All decay channels** can often be used (not only $H \to 4l$ etc)
- **Can adjust the initial conditions**, the beam energy, polarize the electrons and the positrons, and measure precisely the absolute integrated luminosity.
- **No trigger** needed.
- Last – but not least – **theoretical predictions** can be brought under very good control.

The e^+e^- Landscape

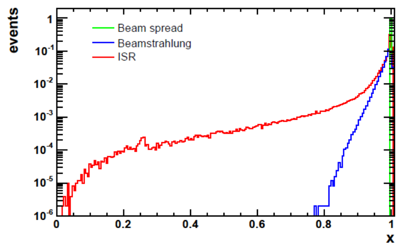


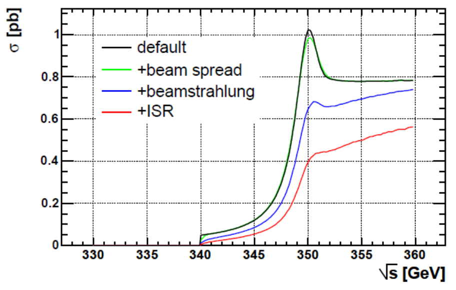


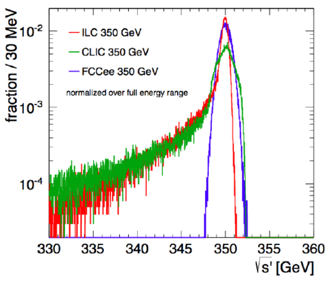
Cross-sections are typically at the pb level.

Luminosity Spectrum

- Experimentally accessible measurements are convolved with effects of ISR, beam spread and beamstrahlung







Luminosity sprectrum should be controlled well at ILC (to < 0.2% differentially using Bhabhas)

m_W Prospects

1. Polarized Threshold Scan
2. Kinematic Reconstruction
3. Hadronic Mass

Method 1: Statistics limited.

Method 2: With up to 1000 the LEP statistics and much better detectors. Can target factor of 10 reduction in systematics.

Method 3: Depends on di-jet mass scale. Plenty Z's for 3 MeV.

Kinematic Reconstruction in Fully Leptonic Events

See Appendix B of Hagiwara et al., Nucl. Phys. B. 282 (1987) 253 for full production and decay 5-angle reconstruction in fully leptonic decays as motivated by TGC analyses.

The technique applies energy and momentum conservation. One solves for the anti-neutrino 3-momentum, decomposed into its components in the dilepton plane, and out of it. Additional assumptions are:

- the energies of the two W's are equal to E_{beam}, so m(W^+) = m(W^-).
- a specified value for M_{W}

$$\vec{\mathbf{p}_{\overline{\nu}}} = a\,\vec{\mathbf{l}} + b\,\vec{\mathbf{l}'} + c\,\vec{\mathbf{l}} \times \vec{\mathbf{l}'}$$

By specifying, M_{W}, one can find a, b and c^2, so there are two solutions.

The alternative pseudomass technique is more appropriate for a M_{W} measurement. It does not assume M_{W}, but sets $c = 0$, similarly yielding two solutions, (a_+, b_+) and (a_-, b_-), leading to PseudoMass(+) and PseudoMass(−) estimators per event.
