

# ***Status: Undulator e<sup>+</sup> source WBS***

***G. Moortgat-Pick, S. Riemann,  
Jim Clarke, Peter Sievers***

## **Outline**

- Status TDR Baseline**
- Transfer 250 GeV**
- Open issues**
- Outlook: undulator collaboration**

# Status TDR lattice baseline

- Rather complete lattice exists for  $\sqrt{s}=500$  GeV
  - source: OMD
  - pre-acceleration  $e^+, e^-$  to 125 MeV (NC)
  - pre-acceleration  $e^+$  to 400 MeV (NC)
  - 5 GeV booster (SC)
  - spin rotator+energy compression
  - DR
- Auxiliary source for commissioning (1% beam intensity)
  - uses microwave photo cathode gun
  - 500 MeV  $e^-$  drive beam on same target
  - about 40 m long
- Lattice has been optimized from capture section up to DR injection
  - maximum transmission but minimum emittance growth

# Status TDR lattice baseline

- Usual beamline instrumentation to measure orbit, emittance, energy spread.
  - Special diagnostics to 'e+ unique systems', e.g. target
  - BPM etc.
  - Performance specifications less demanding than for ML, RTML
- Positron source magnets
  - ~160 dipoles, ~500 quads, ~250 corrector magnets
  - Magnet designs 'straight forward'
  - 27 DC solenoids (for focusing e+ at low energies)
  - 2 SC solenoids for spin rotation
- Dumps (electron and photon beam dump)
  - altogether 9 dumps (2 x tune-up dumps (400kW), 6 x based on solid-metal construction, 1xphoton dump), 16 var. ap. collimators, 1 fixed-ap. collimator, 5 stoppers

# Required TDR lattice updates for Prelab

- Changes
  - instead of 150 GeV undulator drive-beam: 125 GeV drive-beam
  - slight undulator parameter changes (range of  $K \sim 0.85 - 0.92$ )
  - photon energy (1st)  $\sim 8$  MeV instead of  $\sim 10$  MeV
- Maybe Inclusion of  $e^+$  source polarimeter
- Inclusion of final designs for undulator optimization (WP5), rotating wheel (WP6) and OMD (WP7)
  - not under WBS discussion
- ➔ Lattice updates: probably only small manpower efforts needed in prelab, since already a very detailed lattice exists (-> Benno)
- ➔ R&D issues exactly following TDR

---

## Started a list:

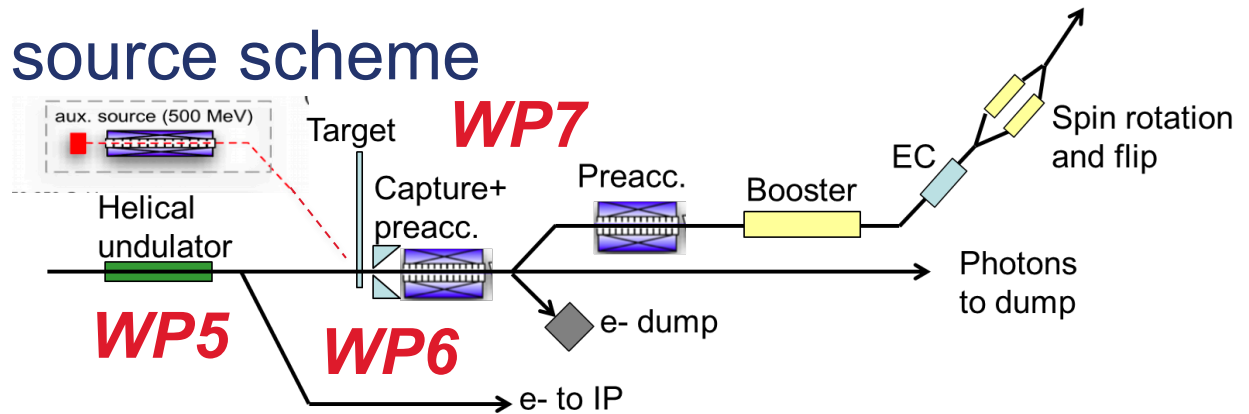

- \* TDR status
- \* update
- \* prelab
- \* FTE

Area	Sub-items	covered in TDR	updates required	Prelab Phase	FTE
System	Lattice	✓	no		
Photon production					
Positron transport					
Booster Linac					
Linac-to-DR Line					
Optic parameter					
Accelerator components	Undulator parameters	✓			
	Target System WP6				
	OMD WP7				
	SW&TW structure	✓	no		
	Magnets:~160 di, ~500 quad, ~250 cor	✓	no		
	Diagnostics: BPM system	✓	no		
	Dumps:9				

---

# Open Issues:

## The polarized e<sup>+</sup> source scheme

Work package	Items
WP-5: Undulator	Simulation (field, errors, alignment, masks)
WP-6: Rotating target	Design finalization, partial laboratory test, mock-up design
	Magnetic bearings: performance, specification, test
	Full wheel validation, mock-up
WP-7: Magnetic focusing system	Design selection (FC, QWT, pulsed solenoid, plasma lens), with yield calculation
	OMD with fully assembled wheel

– Required WBS on these items: Benno's talk+update Peter

# Open Issues for prelab

- Recommendation of Review panel: invest more manpower&money to demonstrate feasibility
    - **should get highest priority**
    - current activities: form/re-new undulator collaboration
    - strong interest and experience
    - lots of experience and mature undulator technology
    - regular meetings
    - involved so far: US labs, EU labs, CERN, Japan (?)
  - Problem:
    - potential money in US: not before end 2023!
- ➔ not really a chance to have prototypes finished in 2024....

# Further news and Conclusions

- Peter: already technical specifications and in contact with Jülich lab+industry
- Simulations for OMD ongoing
- ‘Old’ and ‘new’ collaborations fostered
  
- BUT: we have to get the money
- Labs can only contribute ‘parasitically’ to their ongoing work (as soon as it is not a ‘project’)
- High international prioritization would be desired...

# Back-up

# The conversion target

- Located ~240m downstream the undulator exit
- Undulator photon beam, few  $10^{16}$   $\gamma$ /sec, ~60-70kW
- Only few % of the photon beam power is deposited in the target
- Target design:
  - Wheel (~1m diameter) spinning in vacuum with 2000rpm (100m/s tangential speed) to distribute heat load
  - material: Ti6Al4V
- Target thickness:
  - ILC250:
    - Av. photon energy is O(7.5 MeV);
    - target thickness of 7mm ( $0.2X_0$ )
    - Power deposition ~2kW (nominal Lumi)
  - ILC500:
    - Av. photon energy is O(27 MeV);
    - target thickness of 14.8mm ( $0.4X_0$ )
    - Power deposition ~2kW (nominal L)
- Photon beam hits wheel at  $r=0.5m$ 
  - One pulse with 1312 (2625) bunches occupies ~7 (~10)cm
  - Every ~7-8sec load at same target position
  - in 5000h roughly  $2.5 \times 10^6$  load cycles at same spot

# Cooling of the target wheel

- Water cooling (TDR design) does not work
- Few kW heat deposition can be removed with thermal radiation:
  - heat radiates from spinning target to a stationary water-cooled cooler

$$P \sim \sigma \epsilon A (T_{\text{radiator}}^4 - T_{\text{cool}}^4)$$

$\epsilon$  = effective emissivity

- Ti alloys have low thermal conductivity
  - ( $\lambda = 0.06 - 0.15 \text{ K/cm/s}$ )
  - heat propagation  $\sim 0.5\text{cm}$  in 7sec (load cycle)
  - heat accumulates in the rim near to beam path

# Temperature distribution in target

Average temperature in Ti6Al4V wheel as function of radius  $r$  for different surface emissivity of target and cooler (Cu); Target wheel assumed as disk

Studies (FLUKA, ANSYS) show that such spinning disk stands heat and stress load

# WP6: wheel design (1)

- Material:
  - material tests with load similar as expected at ILC were done using the e- beam at Microtron in Mainz → Ti alloy will survive load cycles for  $\geq 1$  year
  - To be continued to study strength against high cyclic peak load at high T (luminosity upgrade)
  - Include alternative alloys with high T and high strength
- Target geometry
  - Optimize temperatures, stresses, thickness etc. while maintaining the required e+ yield
  - Study influence of eddy currents (heating, drag forces) caused by B field at target from OMD
  - Studies to be done with ANSYS, COMSOL,...
- Lab test of target sector to confirm cooling performance
- Drive and bearing
  - Magnetic bearing for vacuum-tight spinning wheel

# WP6: wheel design (2)

## Drive and bearings

- Radiation cooling allows magnetic bearings
  - A **standard component** to support elements rotating in vacuum.
  - The axis is «floating» in a magnetic field, provided by permanent or electro magnets
  - Allows long time operation at high rotation speed without maintenance
  - Among other things, magnetic bearings are used as Fermi-choppers in Neutron Physics and Spallation Sources.
  - Breidenbach et al. (SLAC) presented at ICHEP2016 a design proposal using magnetic bearing (see backup) for the undulator target
- For the specific ILC-application, a **technical specification** of the required performance and boundary conditions has to be negotiated with the supplier.
  - Specification to be done based on simulation studies

Philipps-Universität Marburg

Principle layout: Ti wheel with diameter 1m, rotating at 100m/s, 2000rpm

Main components: cooling system, magnetic bearing , OMD

Target can be connected with carrier wheel of appropriate material to optimize cooling performance

Layout of wheel and details of target sectors detail mounted onto carrier wheel

- free thermal expansion
- Reduced eddy current
- synchronize rotation with beam pulses by fine tuning to avoid luminosity loss by expansion slots

# An OMD for the Collection of Positrons for the ILC-Undulator driven Source (WP 7).

A feasibility study and preliminary design and engineering parameters.

# Previous Considerations and Design Studies

Long Pulse Flux Concentrator. P. Martyshkin-BINP-2014

Short Pulsed LEP Solenoid.  
 0.83 T, 2.5 kA, 100 Hz

# Pulsed solenoid

Idea presented by P. Sievers at POSIPOL18 and LCWS19, arXiv:2002.10919

- Currently, most favoured option
- Optimization to achieve  $1.5e^+/e^-$

A. Ushakov

Peter started detailed simulations with Matthias Mentink, CERN

# Ref.: M. Mentink-CERN (Priv. Comm. 21.1.2021). COMSOL-Multyphysics Code.

- Operating current: 50.5 kA
- Inductance: 1.4  $\mu\text{H}$
- Stored magnetic energy at full current: 1750 J
- Volume:  $1.1\text{e-}4 \text{ m}^3$
- Conductor cross-sectional area (not including hollow core) :  $7.2\text{e-}5$
- Conductor length: 1.3 m
- Assumed conductor resistivity:  $1.7\text{e-}8 \text{ }\Omega\text{m}$
- Average dissipation, when considering skin effect: 9 kW

Preliminary values for the wheel with  $R=0.5$  m, a peak field of 3.2 T and a pulse of 4 ms.

Due to the pulsed solenoid: Axial peak forces  $K_z$  and av. power  $W_z$ , deposited in the wheel:

$\ll \pm 100$  N/pulse and  $\ll 100$  W.

Due to the velocity of the wheel: Braking force  $K_x$  and power  $W_x$ , deposited in the wheel:  $< 200$  N/pulse and  $< 200$  W av.

# To Do List for OMD and Conclusion.

- Yield to be optimized in the muliti-dimensional «Phase Space»:
- Magnetic peak field and shapes.
- Time stability of the field over the 1 ms by pulse durations of  $> 4ms$ .
- Pulse duration and av. Joule heating and cooling of the coil.
- Magnetic forces and stresses in the coil.
- Life time of the solenoid under cyclic load and radiation damage.
- Volume and surface of the wheel for cooling by thermal radiation.
- Minimize temperatures and stresses in the spinning wheel due to the magnetic field of the solenoid (Laminate the target, iron flux trap).
- Cyclic mechanical loads transmitted to the magnetic bearings.
- Current leads and pulser.

- Maximum input parameters were chosen to exploit the limits of the system: Peak values 50 kA, 5.2 T.
- Realistic parameters: Peak field 3.2 T. Helps a lot in terms of forces and power: factor 2.5 down.
- Longer pulse duration for field stability causes a penalty for the deposited power.
  
- Reliable predictions are possible by established FEM-codes.
- A prototype of the OMD can be built and tested within 2-3 years, provided a pulser is available.
- The mutual response between the spinning wheel and the solenoid can be benchmarked by using a stationary wheel in a solenoid with fast pulses of  $\sim 100 \mu s$  (Magnets used for induction heating?).

Possibilities to optimize the yield by adjusting the field in the target-solenoid gap.

Use the upstream coil as a Bucking Coil «opposite» or as a Booster Coil «twin».

Aperture 4 cm, 50 kA, 7 turns

Design Parameters for the Conical Pulsed Solenoid.	
Half sine pulse duration	4 ms
Peak current	50 kA
Repetition rate	5 Hz
Average electrical power/m	6 kW
Water cooling flow	0.17 l/s
Temperature rise in cooling water	9 K
Peak magnetic field	5.2 T
Field at target	3. T
Field at target with upstream booster coil	4. T
Stress due to magnetic field	40 MPa
Beam effects at nose of the FC at r=1 cm	PEDD 13 J/g *
Average beam power density	600 W/ *
Thermal stress	100 MPa *
Displacement per atom (dpa)	0.15/ 5000 h *

\* Critical values!

Increase aperture to 3 cm. Compensate loss of field by upstream booster coil

# Engineering Design of the pulsed Solenoid: a proposal.

## Layout for Clamping and Retaining the Coil Windings by tie rods

# Cooling of the target wheel

- Few kW heat deposition can be removed with thermal radiation:
  - heat is radiated from spinning target to a stationary water-cooled cooler

$$P \sim \sigma \epsilon A (T_{\text{radiator}}^4 - T_{\text{cool}}^4)$$

- $\epsilon$  = effective emissivity
- Rough estimate: for 2kW power deposition about 0.6 m<sup>2</sup> are needed to keep material at 400<sup>o</sup> C average temperature ( $\epsilon = 0.3$ )
- simulations for temperature distribution in the target wheel cooled by thermal radiation

*Average temperature distribution in a target piece corresponding to 1 pulse length ( $\epsilon_{\text{eff}} = 0.33$ ;  $\epsilon_{\text{Ti}} = \epsilon_{\text{Cu}} = 0.5$ )*

F. Dietrich

*Wheel radius = 51cm*

# Average stress in target, ILC250, 1312b/pulse

ANSYS simulations: Consider spinning target disc, thickness 7mm,  $r_{out} = 51\text{cm}$ , beam hits target at  $r=50\text{cm}$

- Material expansion  $\Leftrightarrow$  high thermal stress in beam impact region
- Stress due to rotation (hoop and radial) is  $<50\text{MPa}$ , in the rim region  $<10\text{MPa}$

Average von Mises stress along wheel radius  $r$

$$\sigma_{vM} < 220\text{MPa}$$

Photon beam impact at  $r=50\text{cm}$

# Drive and bearing

Design Proposal by M. Breidenbach et al, ICHEP 2016:

Bearingless Hysteresis Motors

# Capture optics

- High B field very close to target for high yield
- low (or zero) B field at target to avoid eddy currents
- TDR: Flux concentrator
- Prototyping at LLNL (J. Gronberg)
  - Bmax stable during 1ms pulse (1ms)
  - But  $B(z, t)$ , i.e. luminosity varies during pulse

## QWT

- current design: e<sup>+</sup> yield to low for ILC250

## Pulsed solenoid

- Pulsed B field at target
- increases e<sup>+</sup> yield but
- increases load at target
- only slightly

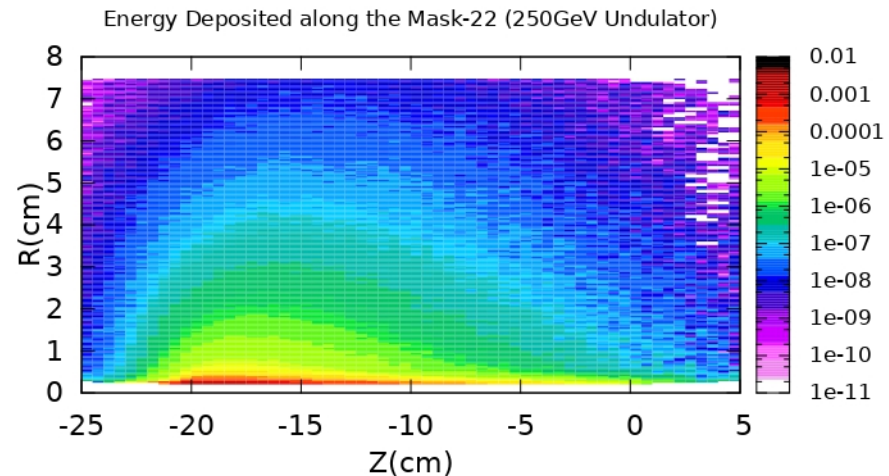

# Power Deposition on Undulator wall must be $< 1\text{W/m}$

K. Alharbi

22 masks to protect undulator wall

## Mask design (Cu)

	Deposited power [W]	PEDD [J/g/Pulse]	$\Delta T_{\text{max}}$ [K/Pulse]

# Target analyses via synchrotron diffraction

T. Lengler,  
BThesis2020

- analyze target materials via scanning as well as synchrotron diffraction methods
- advantage of synchrotron diffraction: both surface as well as structure of targets with several mm thickness can be precisely studied
- Analysis via Synchrotron diffraction: x-rays of 87.1 keV with different beams size

Results of diffraction method:

- Phase transitions between  $\alpha$ - and  $\beta$ -phase in Ti-alloy observed in case of heavy overloading
- Thin foils of Ti and Ti alloys stand high PEDD

Further plans: Target tests with e- of 180 MeV with different materials (W, Al,..)

- synchrotron diffraction at PETRAIII: detailed surface analyses and different angle resolution incl. det. of phase parameters

Target before and after radiation:

$\alpha/\beta$  phase transitions in Ti-6Al-4V:

# ILC250 and GigaZ options

## ILC250:

- 125GeV e- beam requires high K and maximum active undulator length of 231m
  - Upper half of energy spectrum is emitted in cone  $\sim 1/\gamma$  masks are necessary to limit the energy deposition in the undulator walls to 1W/m

## GigaZ: see arXiv:1908.08212

- 3.7+3.7 Hz scheme: use 125GeV e- beam for positron production, alternating with 45.6GeV beam for physics
- A 45.6GeV e- beam has low power, photon energy is low → no problem for target.

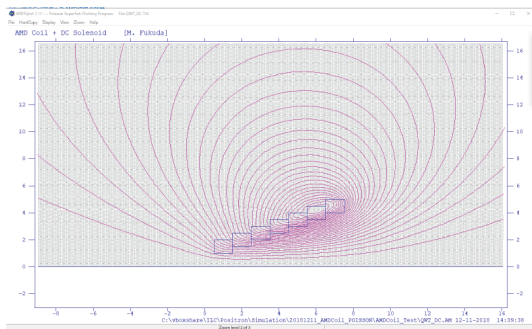

# OMD: Pulsed solenoid

arXiv: 2002.10919

Idea presented by P. Sievers at POSIPOL18 and LCWS19, see also proceedings

## Pulsed B field at target

- increases e<sup>+</sup> yield
- Increases load at target only slightly

Peak magnetic field	5.2 T
Field at target	3 T
Field at target with upstream booster coil	4 T
Stress due to magnetic field	≤ 40 MPa
Beam induced effects at entrance of the solenoid, r=1 cm	PEDD 13 J/g
Average beam power deposition	600 W/cm <sup>3</sup>
Thermal stress	≈ 100 MPa
displacement per atom (dpa)	0.15/5000 h
