CALICE Collaboration Meeting September 10<sup>th</sup>, 2021

### **AHCAL Technological Prototype**

Purpose

**Event selection** 

Finding track segments

Track segment results

MC comparisons

Calibration

CALICE Collaboration Meeting Track Segment Analysis in AHCAL F.Corriveau 10 September 2021 ---

### Content

### Purpose

Particle showers produce very large amounts of secondary particles.

Would it be possible to use these in principle "minimum ionizing particles" (MIPs) to establish an *in situ* calibration of the detector?

In the **ideal** case, all detected particle tracks or segments would behave the same way, independent of their type or energy. This is needed because the mix in a real detector would be unknown.

In **practice** this cannot be that simple, there might be dependencies, there will be corrections due to angles and other systematics ...

But how far can one go? A "simple" robust method is proposed here.

Data from June 2018, taken at the CERN SPS, with  $e_{,\pi,\mu}$  beams from 10 to 200 GeV

### **Event Selection**

### **Shower Hits: Clusters**

![](_page_4_Picture_3.jpeg)

## **Finding Track Segments**

- The method uses **connectivity** properties and the inertial tensor. with hit **Connectivity**: how many neighbors does a calorimeter cell have in 3D (from 0 to 26)?
- 1) Reject hits with connectivity < 1: outliers or isolated hits
- 2) Reject hits with connectivity > 8: shower core(s) [the start of the shower comes for free]
- 3) Refresh connectivity 3D map
- 4) Minimum chosen for segment candidates from the remaining clusters: 4 hits. (<4 is deemed too few to identify reliably and >4 will reduce the statistics) [systematic]
- 5) Primary track of the event is specially tagged, since most likely not to be a MIP

![](_page_7_Picture_4.jpeg)

### **Track Segment Identification**

The surviving clusters are a list of hits, each a 5D entity (t,x,y,z,E). Clusters are characterized with the inertial tensor:

$$\mathbf{I} = \sum_{i=1}^{N} \begin{pmatrix} y_i^2 + \\ -x_i \\ -x_i \end{pmatrix}$$

which can be diagonalized:

$$\mathbf{I} = \sum_{i=1}^{N} \begin{pmatrix} e_1 & 0 & 0 \\ 0 & e_2 & 0 \\ 0 & 0 & e_3 \end{pmatrix}$$

F.Corriveau Track Segment Analysis in AHCAL CALICE Collaboration Meeting 10 September 2021

[time not used yet]

 $+ z_{i}^{2} - x_{i}y_{i} - x_{i}z_{i} \\ x_{i}y_{i} \quad x_{i}^{2} + z_{i}^{2} - y_{i}z_{i} \\ x_{i}y_{i} - y_{i}z_{i} \quad x_{i}^{2} + y_{i}^{2} \end{pmatrix}$ 

[weights E<sub>i</sub> are folded in]

### yielding the longest axis via $e_1$ . A loose cut of $e_1/(e_2^2+e_3^2)^{\frac{1}{2}} < 0.1$ enforces straightness.

![](_page_8_Picture_14.jpeg)

### **Number of Track Segments per Event (averages)**

<b>Beam Energy</b>	Muons	Electrons	Pions	
10 GeV		$1.04 \pm 0.22$	$1.50\pm0.72$	
20 GeV		$1.17\pm0.43$	$1.72\pm0.90$	
30 GeV		$1.06\pm0.30$	$1.77 \pm 0.95$	
40 GeV	<b>~1.26</b> (broken or double)	$1.05\pm0.25$	$1.89 \pm 1.04$	
50 GeV		$1.10\pm0.39$		
60 GeV		$1.07\pm0.31$	$1.91\pm1.07$	
70 GeV		$1.10\pm0.39$		
80 GeV		$1.17\pm0.51$	$2.00\pm1.14$	
90 GeV		$1.21\pm0.56$		
100 GeV		$1.28\pm0.66$		
120 GeV			$\textbf{2.01} \pm \textbf{1.16}$	
160 GeV			$\textbf{2.03} \pm \textbf{1.18}$	
200 GeV			$2.07\pm1.20$	
Slow increases with anarow as expected				

### Slow increase with energy, as expected.

Pions

10 September 2021 - Track Segment Analysis in AHCAL

11

![](_page_11_Figure_0.jpeg)

Option 1: assume this is exact (risky) and make the correction

Option 2: (chosen) fit the data with:  $E_{\ell}$ 

See how well the dependence

The fitted  $E_{0^o}$  value per layer becomes the "calibration reference number" (in MIP units)

F.Corriveau - CALICE Collaboration Meeting - 10 September 2021 - Track Segment Analysis in AHCAL

### **Geometrical Angular Dependence**

Path length in tile is a function of the polar angle  $\theta$ :

 $\mathcal{L}_{\theta} = \frac{\mathcal{L}_{0^{o}}}{\cos\theta} \quad \text{ so that one expects: } \quad E_{\theta} = \frac{E_{0^{o}}}{\cos\theta}$ 

$$E_{ heta} \approx E_{0^{o}} (1 + \frac{1}{2}\theta^{2} + \frac{5}{24}\theta^{4} + ...)$$
  
e holds:  $E_{ heta} \approx E_{0^{o}} (1 + c\theta^{2})$  is c=½?

## Summary of $E_{0^o}$ Results

80	90	100	120	160	200
Beam Energy (GeV)					

![](_page_14_Picture_6.jpeg)

## **Open Questions & Systematics**

- 1) Muon rate discrepancy Data/MC: attributed to double events or broken clusters.
- 2) Angle  $\theta$  dependence for pions: the "c" factor is ~5 times too large, which however does not affect the extrapolated values (same for Data and MC).
- 3) Muon numbers lower: lack of time to be studied but offered for comparison.
- 4) Values are  $\theta$ =0 are systematically lower: related to muon beam contamination?

dependence, yielding:

All results are preliminary. Open questions (to be investigated) remain for segments:

The following systematic errors for  $E_{0^o}$  have been estimated: (1), (4) and beam energy

Electrons:  $2.73 \pm 0.08 \pm 0.09$  MIP  $2.50 \pm 0.13 \pm 0.05$  MIP

some discrepancy electrons-pions

# A very similar study has been performed with DHCAL and presented at the 2018 CALICE Collaboration Meeting in Mainz: (see extra slide for other previous CALICE studies)

![](_page_16_Figure_2.jpeg)

![](_page_16_Picture_4.jpeg)

## **Summary and Outlook**

should be attainable.

- The possibility of using secondary track segments for *in situ* calibration in a detector has been investigated with AHCAL.
- The potential is there but some effect have still to be understood and the statistics required for absolute single channel calibration may be overwhelming. Looking at single cells is the next step.
- Still, given a stable and reliable trigger in a detector, a constant self-monitoring of the data relative calibration at the few-% level
